26/5714

INDEX

A		Page.		Page.
Abangarez Gold Fields of Costa Rica.....	34, 206, 358, 511, 666, 442,	1032	Alkaline cyanides, electrolysis of aqueous solutions of the simple	927
Company Report		833	Solution, clarifying with basic lead acetate	515
Abbottlakoon Mines, Ltd., company report.....		595	Alleghany district, California, geology of	22
Abosso mine, West Africa	270,	892	Allen, A. W. Colloids in ore dressing.....	109
Acacia Mining Co., Colorado		830	Ditto..... Simplification of gold-ore treatment.....	254
Accident prevention	Editorial.....	955	Ditto..... Solution control in cyanidation.....	448
Rules, Copper Queen Co.'s mine, Arizona.....		634	Allouez Mining Co., Allouez, Michigan.....	635, 743, 791, 991
Accident Gold Mining Co., Subil mine, French Gulch, California		472	Alloy, elianite	170
Accidents, coal-mine in United States		864	Osmium-platinum, a new..... F. Zimmermann.....	533
Compensation for		226	Alloys, melting points of copper.....	890
Workingmen's compensation	Editorial.....	755	All-sliming mill	136
Acid mine water		876	Alluvial gold	46
Acidity, counteracting		750	Alluvials, successful salting of..... C. S. Haley.....	1000
Acme mill, Sears'		128	Alta Berta Gold Dredging Co., California	357
Adams, John Colt, death of		703	Alta Consolidated Mining Co., Utah	547
Addition, A. Sydney. Under-estimating the cost of milling plants—I, II, III, IV.....	88, 138, 263, 301,	620	Capital stock increased	666
Administration and Mexico		386	Altman, Benjamin, legacy.....	674
Ditto	Editorial.....	366	Aluminum	912
Advertising results of company meetings.....	Editorial.....	1	H. D. Avis' patent for coating	306
Aerial tramway across Andes mountains, South America.....		978	Industry	790
Tramway, Irvinebank		382	Powdered	170
Tramway, one-rope	Editorial.....	41	Precipitation process	217
Tramway, Saline Valley Salt Co., California.....		210	Alunite	443
Aerolites		876	Alvarado Mining & Milling Co., Mexico	988
Africa, copper in Central		585	Amador Copper & Gold Mining Co., Montana	947
Phosphate		501	Amalgamated Copper Co., Butte, Montana.....	624, 865, 980
Agitation		154	Amalgamated Zinc (De Bavay), Ltd.....	381
Slime..... H. B. Wright.....		464	Company report	706
Agitator, Dorr..... John V. N. Dorr.....		193	American canyon, Humboldt county, Nevada, placer camp	373
Symmes..... P. G. Spillsbury.....		467	Enterprises in South America, and American manu-	
Ditto..... Whitman Symmes.....		92	facturers	Editorial..... 518
Trent..... Donald E. Irvin.....		821	American Electrochemical Society and American In-	
Ditto..... Walter Techow.....		385	stitute of Mining Engineers, New York section	
Agricola: an appreciation..... F. Lynwood Garrison.....		218	meeting	865
On fissure veins		38	American Fireproofing & Mining Co., Wyoming, organ-	
Ahmeek Copper Mining Co., Kearsarge, Michigan.....		991	ized	1031
Dividend	635, 791,	246	American Flag mine, Utah	433, 437, 987
Air-compressor, Sullivan angle-compound.....		795	American Institute of Mining Engineers and affiliation	
Pressure in smelting	R. H. Shaw.....	145	with Mining and Metallurgical Society of America	
Pressure in smelting		145	Editorial.....	329, 366
Ajax Gold mining Co., Colorado		870	Butte meeting	Editorial..... 292
Mine, Victor, Colorado, electric mine-signal system.....		340	Colorado section, meeting at Denver	824
Akin, A. D..... Olancho county, Honduras.....		49	Ditto	Editorial..... 797
Alabama, mineral production		1018	Iron and Steel section meeting	662
Alaska, Aleutian group		116	Ditto	Editorial..... 518, 825
Coal		742	Montana local section, meeting	865
Distances to new placer districts		1028	New York section, joint meeting with American	
Fairbanks district output 1913		906	Electrochemical Society	785
Fairbanks district stamp-mills		945	Spokane and Montana sections	202
Fineness of gold at		341	American Lead & Zinc Co., Illinois.....	365
Glaciers		361	American Mining Congress	665, 696
Gold dredges		876	Philadelphia meeting	760
Gold placer district, new		835	Resolutions	431
Gold placer production		876	American Smelters Securities Co.	471
Gold placers		627	American Smelting & Refining Co.	782
Goldstream, No. 17	Editorial.....	41	Arsenic limit on Cobalt ores	398
Home rule in		906	Dividend	522
Hot Springs district output 1913		819	El Paso smelter	666
Innoko and Iditarod districts		160	Garfield plant	524
Koyukuk-Chandalar region		330	Hayden smelter	944
Lode mining in Interior	Editorial.....	793	In Mexico	197, 387, 474
Matanuska coalfields		355	American Zinc, Lead & Smelting Co., 197, 387, 474	
Metalliferous mining in 1912	Editorial.....	252	Amy-Matchless Mining & Milling Co., Arizona, organized	907
Mining laws		699	Anaconda, briquetting of slime at	838
Nelchina placer district		828	Leaching process	830
Nome storm	588, 627, 699,	797	Anaconda Copper Mining Co.	114, 166, 541, 542, 635, 786, 791, 824, 825, 980, 991
Ditto	Editorial.....	742	Dividend	541
Oil		918	Geologic notes underground	940
Pioneer electric locomotives in		953	Nettle silver mine	824
Proper outfitting for trails, and government super-		86	November copper production	877
vision	Editorial.....	210	Smelter	659
Railway construction		288	Tropic shaft	980
Rock-drilling contests		906	v. Alice mine	865
Ruby district output 1913		819	v. Butte-Ballaklava Copper Co., amicable adjust-	980
Ruby, Innoko, and Iditarod districts		945	ment	659
Shushana district	236, 355, 391, 627,	329	v. Pilot-Butte Mining Co.	597, 634
Ditto	Editorial.....	507	Washoe plant	151
Shushana district, Canadian Geological Survey report		1028	Anakie sapphire fields of Queensland..... Lionel C. Ball.....	1011
Shushana district, distance to		828	Analyses, dikes on Rand	126
Shushana district output		966	Of pyrrhotite	
Shushana-Glacier trail		906	Analysis for constituents of zinc ores, combined method	
Tanana valley output		1021	of	Frank A. Bird..... 15
Wagon-roads and trails	Editorial.....	330	Of black powder and dynamite	695
Willow Creek district		335	Anantapur Gold Field, Ltd., India	311
Willow Creek district, lode mining in	Sumner S. Smith.....	110	An-Chi ironfield	C. Y. Wang..... 616
Winter work in	A. E. Garvey, T. A. Rickard.....	336	Anchor Tin Mining Co., Tasmania	993
Alaska Free Gold Mining Co.		391	Company report	288
Alaska Gastineau Mining Co.	116, 184,	879	Andesite, Tonopah Belmont mine, Nevada	126
Ditto	Editorial.....	541	Aneroid barometer	287
Alaska Gold Mines Co.		879	Anglo-French Exploration Co., company report.....	798
Ditto	Editorial.....	184	Annalist, New York Times	720
Preparatory Work of..... Grant H. Tod.....		906	Annealing of gold	761
Suit regarding		336	Antelope Gold Mine, Ltd., Rhodesia	286
Alaska Gold Quartz Mining Co.		879	Company report	838
Alaska Juneau Gold Mining Co.		880	Anthraxite, mining cost and profit	12
Plans of the..... F. W. Bradley.....		906	Production, Pennsylvania	912
Alaska Mexican Gold Mining Co.	199, 355, 627, 868,	906	Antimony	250
Alaska Treadwell Gold Mining Co.	199, 355, 627,	906	Imports into United States	846
Ditto	699, 868,	879	Aqueduct, Catskill	927
Dividend	Editorial.....	1028	Aqueous solutions of the simple alkaline cyanides,	
Electric locomotives		918	electrolysis of	896
Stamp-mill returns		742	Aramayo Francke Mines, Ltd., Bolivia	615
Alaska United Gold Mining Co.	199, 355, 627, 784,	945	Arba Tin Mining Co., Tasmania	1025, 1031
Albert Oil Shales, Sussex, New Brunswick		826	Ardmore Oil Co., South Dakota	
Aleutian group, Alaska		116	Are there jobs enough to go around?.....	900
Alex Scott mine, Butte, Montana		195	F. Sommer Schmidt.....	252
Algeria, mining in		891	Argonaut Mining Co., v. Kennedy Extension Co.	472
Algoma Mining Co., company report.....		556	Arizona metal production	627
Alice mine v. Anaconda Copper Mining Co.		865	Mining industry	1028
			Patent on mining claim	
			Arizona Commercial Copper Co., Globe, Arizona.....	906
			Mine	199, 236, 318, 866
			Arizona Copper Co., Ltd., Morenci, Arizona.....	279, 544, 991
			627, 635, 583, 791, 868,	86
			Inspection department	Editorial..... 984
			Powder explosion	923
			Smelter	

	Page.		Page.
v. County of Greenlee	544	Billingsley, Paul.....Georgetown mining district and	
Arkansas, Blue, and Magazine mountains	838	the Southern Cross Mine, Montana....	546
Diamonds in	79	Bingham Mines Co., Bingham, Utah	196
Mineral products	779	Bird, Frank A....Combined method of analysis for	
Zinc ore deposits in Boone and Marion counties.		constituents of zinc ores	18
Kirby Thomas	854	Bisbee copper ores, Los Angeles Chamber of Mines and	
Arrastre, an old	898	Oil	1028
Arsenic in United States	250	Bishop Creek mine, California, cyanide plant.	946
in Virginia	622	Bismarck Consolidated Mines, Black Hills, South Dakota	1028
Limit on Cobalt ores, American Smelting & Refin-	14		
ing Co.	782		
Abestos deposits, Urals	528	Bismuth in United States	506, 660, 826
Production in Canada	210	Tin-wolfram ores from Tasmania	250
Production in United States	210	Black-damp	461
Russia	362	Black Diamond, Alberta, Canada, oil discovery	40
Virginia	15	Black Hills, South Dakota, mineral production	903
Ashanti mine, West Africa	892	Mines	826
Gold production	270	Black Oil Mines & Mill Co., Tuolumne county, Califor-	660
Ashburton Mining Co., dredge, California	829	nia	
Assay office, United States at Helena, Montana	659	Cyanidation	628
Assaying, iron-nail method	170	Black Range, Western Australia	757
Associated Gold Mines, Ltd., Western Australia, 235, 433,		Black Warrior, Gila county, Arizona	594, 655, 835,
594, 835,	911	Blackwater Mines, Ltd., Blackwater, New Zealand, Com-	906
Cobalt properties	1032	pany report	
Company report	286	Blaine county, Idaho, geology	555
Costs at	327	Blanquer, Juan	629
Cyanidation	759	Blast-hole drilling in open-pit copper mining	777
Power-plant at	346	Blasting, electric	643
Associated Northern Blocks, Ltd., Western Australia	911	Charles S. Hurter	734
Victorious leases, Oro Banda, 235, 425, 433, 469, 594,		Block Mines Co., Arizona	279
626,	781	Bluebell mine, British Columbia	158
Atbasar and Spassky copper properties, Siberia	580	Blue sky law, South Dakota	826
Athabasca Landing, Alberta, Canada, oil discovery	903	Bolcaza Gold Mines, Hungary	1021
Atkins, G. H....Duty on cyanide salts	428	Boilers, graphite useful in steam	38
Atlas mine, Tuttletown, California	117	In reverberatory furnace flues, waste heat.	
Attorney's fees	481	Stirling v. Babcock & Wilcox	575
Auckland province, New Zealand, gold and silver pro-		S. Severin Sorensen	864
duction	494	Boleo, Companie du Santa Rosalia, Baja California,	
Australia, Bendigo, gold production	296	Mexico	635, 791,
Compensation Act	105	Boleo Copper Co., Mexico	991
Copper production	78,	Boleo copper mine, California	358
Deep mining in	729	Bolivia, Aramayo Francke Mines, Ltd.	430
Mineral production	693	Diamond-drilling at Poderosa mine. C. L. Severy	896
Mines, ore reserves of	672,	Mineral exports	338
Northern Territory, new mining ordinance	738	Minerals in	467
Radium ores in	655	Railroads and transportation problems in	100
Sydney Stock Exchange, new rule	500		
Victoria, mining law	232	Railway	G. W. Wepfer
Zinc smelting in	867	Tin production	163
Australian capital abroad	1024	Transportation problems in	417
Tin mine, Tasmania	776	G. W. Wepfer	694
Austria coal mine fatality rate	867	Bonanza King	161
St. Joachimsthal, radium from pitchblende	616	Bond, Marshall....Prospecting by the Government	582
Automobile hoist	876	Borax Consolidated, Ltd., in Peru	75
Avis, H. D., patent for coating aluminum	403	Borax production in 1912	324
	150	Boston & Idaho Mining Co., Boise basin, Idaho	590
	306	Boston & Montana Copper Mining Co.	195
		Boston & Montana Development Co.	388
		Railroad	542
		Boston-Butte Copper & Zinc Co., formed	824
		Botalack mine	980
		Boulder No. 1, Western Australia	594, 835,
		Boulder Perseverance, Western Australia	594, 835,
		Bouse & McMahon mine, Arizona	1028

EDITORIAL

FOLLOWING the articles on the 'Organization of Smelting Enterprises' printed in April, we publish this week one on 'Building a Reduction Plant,' by Mr. Herbert Lang, who speaks from an experience that lends much weight to his words. This will be followed in turn by some account of the pitfalls that have been met in actual construction by Mr. A. Sydney Additon, with especial reference to the building of plants of moderate size in remote and difficult situations.

BRADEN Copper Company figures attract keen interest in the United States where this great undertaking in Chile is considered the probable forerunner of many profitable enterprises. We print this week the substance of a new report upon the property by Mr. Pope Yeatman, whose general account of the deposit we published December 16, 1911. Mr. Yeatman's revised figures of ore reserves show 44,000,000 tons containing 2.65 per cent copper, as against a previous estimate of 23,000,000 tons at 2.50 per cent. A broker's circular in New York says that this "shows the ease with which tonnage is added at the mine," which just raises the question whether *Life* is to have a rival.

ADVERTISING the results of company meetings is common in England, but is sufficiently unusual in the United States to warrant calling attention to the announcement of the Minerals Separation American Syndicate, Limited, appearing in this issue. In these days when company success depends upon public support, expenditure for publicity is as legitimate as for raw materials. The danger to be guarded against is the placing of paid matter in the reading pages, the disguising of advertisements. That has been a common practice in the United States, though not, we are glad to say, one adopted by technical journals. The day for such misbranding is rapidly passing. The great public service corporations find it better to take paid space and fill it with plain statements of fact, even in newspapers that editorially oppose their policies, than surreptitiously to own weak journals. The public is quick to detect and to discount tainted news. And a reputation for printing it kills the influence and therefore the income of a paper more swiftly than most violent, but evidently honest, partisanship. The advertising pages of a good technical journal afford a medium for reaching an especially thoughtful and influential audience, but to do so effectively the advertiser must have a message of real import and must tell it plainly. To those who have such a message, we extend a welcome.

The Hall Sulphur Process

Copper metallurgists everywhere, but especially in California, will be keenly interested in the Hall process for dealing with the sulphur in smelter fume, with which the First National Copper Company is about to undertake experiments upon a working scale at its smelter at Coram, California. Mr. William A. Hall, who has devised the process, is a graduate of the Massachusetts Institute of Technology, and a chemist of distinction who has made notable successes in the field of industrial chemistry, being a cousin of the chemist of the same name who devised the process for the production of aluminum by electrolysis of bauxite in a fused bath of cryolite. The Hall sulphur process is essentially a controlled oxidation; the sulphide ore being roasted in a specially-constructed furnace in an atmosphere of reducing gases and steam at a temperature between 700 and 900°C. As a result, the metallic bases are oxidized, but the sulphur, owing to the dissociation of the steam, escapes without becoming oxidized and, passing off in the fume in the form of 'flowers of sulphur,' is easily collected. Careful tests made under the direction of Messrs. C. F. Chandler and A. L. Walker, indicate that the chemistry of the new process is sound, Mr. Walker finding that ore containing nearly 40 per cent of sulphur was roasted to a sulphur content of 3 to 5 per cent at a rate which indicates that approximately the same tonnage per square foot of hearth area can be handled in this way as is done in current practice with the ordinary type of McDougall furnace. No data have been made public as to the fuel consumption to maintain this roasting speed, exact information as to this critical point being one of the objects of the large-scale experiments about to be started at Coram. The collection of the sulphur will be done by the aid of the Feld washer, though the possibilities of collection by means of the Cottrell electric precipitation process are also to be tested. The process will at first be applied to the McDougall roasters.

The large question involved is, of course, the disposal of the sulphur to be produced. Application of the process to all the ore and operation at the rate maintained at Balaklala in 1910 will involve the production of about 250 tons of sulphur per day, or somewhat in excess of the present visible market, assuming that the sulphur can be laid down at points of consumption at a price which would enable it to supplant the pyrite now in use, as well as the rather limited amount of Japanese and Louisiana sulphur now being used in California. The estimated cost of sulphur production is placed at \$5 per ton at a maximum, at which rate the sulphur would easily be able to dominate the market and perhaps increase consumption, as a lower selling price commonly does. In any case, any financial loss, not to exceed $\frac{1}{2}$ cent per pound of copper produced, for example, incurred in the production of sulphur may properly be charged to the cost of smelting under the conditions obtaining in Shasta county. Under previous conditions of operating at Balaklala, a production cost of 10 cents per pound of copper produced was estimated, though operat-

ing difficulties caused it to be somewhat exceeded in practice. The new process, if it proves feasible, will meet fully legislative restrictions, and if the cost of operation proves sufficiently low, will solve the smelter-fume situation as far as the First National is concerned. It is proposed to spend considerable sums on the experimental work, under the direction of Mr. H. F. Wierum, who has had extensive experience with the Tennessee Copper Company, and the prospect of success seems decidedly favorable. But, like the manufacture of sulphuric acid from smelter fume, the process is not one which is of universal application, as its general adoption would at once swamp the market on which dependence is placed for meeting the cost of operation. The foreign rights to the Hall patents have been acquired by the Sulphur Company, Ltd., and the American rights are controlled by the Federal Sulphur Company, Ltd. We wish both companies the fullest measure of success in their efforts to meet a situation trying in the extreme to copper metallurgists throughout the world.

Fourth of July

Once more the 'Glorious Fourth' is with us, and from the great cities of the United States to the borderlands of civilization, bunting is being hung on the outer wall and the American people are joining in the celebration of the Nation's birthday. Other holidays may come and go, but the one red-letter day of the year, the one from which time is dated in the mining camps, is the Fourth of July. It stands out as the oasis in the summer months when the miner can forget for 24 hours the stopes and can devote his entire energies to celebrating. Probably in no other type of community is Independence day more thoroughly celebrated than in the mining camp. Here the festivities are as various as the changes of the kaleidoscope, and the miner gives himself up to recreation which ranges all the way from an over-indulgence in "the cup that clears today of past regrets and future fears," to general picnics with the accompanying liberal garnishing of patriotic sentiment by the camp spellbinder. The nipper and the general manager, united by the ties of patriotism, rub elbows in 'setting-off' fireworks, and on common ground decide questions of superiority in matters of marksmanship and athletics. Outside of the possible barbecue, the features of the day around which the greatest attention centres are the athletic games, which are planned to afford such a variety that everyone may participate regardless of their past performances on the athletic field or prowess in the recognized sports, for near-sports are given a prominent place in the order of the day, and the three-leg race and greased-pig events attract more attention than the 100-yard dash and the hurdles. Then there is the rope-climb, the shot-put, turkey shooting, and many another opportunity for each to shine. And always the band plays its sprightliest.

The feature of the day's program, however, is the drilling contest, as it is this contest that carries with it, if not an olive wreath, at least a purse and a reputation. This is the one contest to which the mining

industry makes claim as its own, and the winning of the drilling contest is to the miner what the Marathon is to the runner, or the roping contest to the cowboy. No one knows how old the hand-drilling contest is, but every miner has watched with strained interest as the drill ate its way into granite while the umpire announces the passing minutes. We believe the best record is that of the Amalgamated 3-hand team, 59½ inches in 15 minutes, made at Calumet, Michigan, in 1911. How widespread is the interest in such contests is suggested by the picture below of a Fourth of July celebration at one of the Oriental Consolidated mines in Korea. While the dress of the onlookers is unusual, the rest of the scene is natural enough, even to the five-gallon

there will be 'three baggers' and close decisions that will provoke hot contention. Whether the Constitution follows the flag is open to debate; but there is no question that close behind 'Old Glory' comes the baseball score. Wherever nine North Americans are gathered together there is a pitcher, a catcher, and a full complement of basemen and fielders. Japan's management of battleships was not more convincing of her Westernization than her enthusiasm for baseball, and whether Stanford wins or loses at Tokyo today, sound friendships will be formed.

It is always hard to leave a ball game, but we really must go to supper (never dinner at the mine), and besides there is the dance in the evening. If we are not ready and dressed in our best, who knows

CELEBRATING THE FOURTH OF JULY IN KOREA.

kerosene can converted into a water bucket. These Korean drillers, by the way, make good records, cutting their 30 inches and over in 15 minutes and contesting as stoutly as any 'Peerless' man or 'Shad.' As hand-drilling is giving way to machine work, so are hand-drilling contests being displaced by competitions between machine drills. The first of these we believe was held on the Fourth of July 1902 at Idaho Springs, Colorado. The machine contests are longer but less dramatic. One misses the play of muscle and the display of brand new undershirts usually worn by contestants on such occasions.

But we have lingered over-long perhaps at the drilling. There are still the hose-cart races to be run, the ladder-climbing contests, and the picnic dinner. After that is the inevitable baseball game, between rival camps, where distances are not too great, and between mine and mill where geography must be considered. Today, we doubt not, from the Davis pyrites mine of Massachusetts, to Masbate

but that Katie, the black-eyed waitress, may tire of delay and go on with Mike the 'mucker.' It will never do to be late. For those who do not dance, and even in a mining camp there are such, or perhaps as the sole attraction, there is that friendly glove contest between foundry and saw-mill. Seated expectant by the ringside there is a good evening's fun to be enjoyed, with many a pretty give and take. Always there is the half thought that a new 'white man's hope' may shine forth at the end. Tired and sleepy, we at last reluctantly go to bed, happily if with no head that hangs over on the morrow and makes food look repellant while the throat notes anew the dryness of the desert. The old custom of dedicating the Nation's birthday to drunkenness is gradually giving way to one of making it a day of healthy sport; and in the turning away from routine thoughts and work, we trust that each will find time for a quiet bit of thankfulness to our forefathers whose sacrifice made possible our Country.

Building a Reduction Plant

By HERBERT LANG

When the plans and details of a proposed works are sufficiently advanced, the engineer sets about the preparation of drawings and specifications of the different articles required, with the view of obtaining bids for supplying them. By far the greater number of such articles, being of ordinary manufacture, do not require to be designed, while their specification may consist of the merest framework of words. Things of special manufacture, which should be as few as possible, require very exact drawings and specifications, and herein lies a great deal of work for the designer, all of which must be completed before the plans are submitted to the builders. It is not well to ask bids from many firms. Scarcely ever is it advisable to call upon more than two or three, for reasons which will be more apparent to the experienced than to the casual reader. In such business undertakings as the erection of a large metallurgical works, it is policy to avoid publicity as far as possible. The engineer himself, whose drawings may represent the fruit, perhaps, of years of study, feeling that they mark a distinct advance in the art, has a natural wish to withhold them from the sight of manufacturers who, like many that might be named, make a practice of copying (in effect stealing) all original drawings that come to their shops. Again, there is much time lost when a large number of firms are taken into the competition, owing to the number of explanations that are required to be given, and to other causes.

Choice of Contractors

It is common for the inexperienced individual or company to express a preference for the work of some particular builder, especially some much advertised concern with whose name they have become familiar, but of whose work they may know absolutely nothing. Not infrequently they may propose to put the whole matter of constructing the machinery, and even of setting up the plant, in the hands of some favorite iron works. This is a situation that calls for extreme tact on the part of the engineer, who may feel the impolicy of employing the firm in question, without being able to communicate his views to his own employers. The policy of certain large builders in the United States is often quite unfavorable to the interests of engineers and employers alike. Their practice frequently is to suggest and bring about changes in the plans, to urge heavier and more costly machinery, to pooh-pooh the ideas and work of rival concerns, and finally to cast discredit on the original designer of the plant under consideration, provided that by injuring his standing with his employers they may advance their own interests. All this has its effect upon tyros, already awestricken by the fame of the bidding firm, and it not infrequently happens that the plans upon which the engineer spent anxious months are discarded, and the manufacturing concern is practically given *carte blanche* to construct the works. It can

easily be seen that such proceedings are as little to the advantage of metallurgy at large as they are to the true interests of the machinery buyers. Aside from this, there is the natural and less reprehensible tendency on the part of all builders to increase the magnitude of the orders (and consequently their profits) at the expense of the purchaser, whom it is the duty of the engineer to protect. The firms most difficult to deal with are those which pose at once as builders of machinery and as original designers of plants. Such concerns produce only designs which embrace their own machinery as constituent parts, and as a rule will assume no responsibility as to the appropriateness of their designs, while at the same time they declare that they will not be responsible for the success even of their own machinery unless their designs also are accepted. This illogical stand cannot deceive the engineer, but appears sufficient to take in many of the more credulous sort of buyers, to the extent of giving a single order, never repeated, for machinery and plans.

Making the Plans

During the preparation of the plans and the construction of the works, there are times when it becomes advisable for the engineer to call for outside assistance, especially in matters of mechanical engineering, in which he may not be sufficiently versed. At such times the resources in skill and apparatus, which well conducted and equipped iron works possess, become of great use. When such a course becomes necessary, it is well to use great discrimination in the selection of a suitable house. With some an application leads simply to the handing over of every detail of construction to people who are not in every way fitted for it. As a general thing, the large machinery houses are acquainted with only the mechanical engineering side of the questions, there being rarely any real metallurgical skill within the concern, and it often happens that the quality of brains which such concerns place at their customers' disposal is of the most ordinary sort. It is far better to avoid such biased and incapable aid. The experience in this matter is that the smaller iron works, especially those making no pretense to extraordinary skill and ability in designing and building plants, are of far more assistance, chiefly because the problems are taken up by the principal officers of such works, who are apt to be men of high attainments in general engineering, and who, having no specialties of their own to uphold, have with more ability far less bias than the mediocre and prejudiced salesmen, draughtsmen, and what-not who perform that kind of task for the larger makers. No one but a metallurgist can ever know how the progress of the art has been hampered and delayed by the disposition of the larger makers to hang to their antiquated drawings and patterns; or by their employment of solicitors and clerks in the place of skilled engineers; or by their boundless

and absurd claims of improvement. Making the largest allowance for the credulousness and gullibility of the mining public, it is difficult to understand how such claims can bring business.

Purchase of Machinery

Speaking generally, then, it would seem that the preferable way to proceed in the construction of the reduction plant would be, after the plans are advanced sufficiently, to ask tenders from two, or at most three, iron works of fair repute and of known skill and versatility, and select as the maker of the desired apparatus that one which combines the advantages of a low, but not too low, price with a location not so far from the proposed works that repair parts for the machinery cannot be had quickly. By no means should the successful bidder be required or even asked to erect the works, for this can always be done better and cheaper by the purchasers, with the added advantage that the men who are to run the plant can generally be had to set it up, whereby they become acquainted with its peculiarities, much to the betterment of the running. Let the greater part of the machinery be bought in the open market, and let it be set up as soon as it arrives, without waiting for other parts. By no means put off the purchase of portions that are certain to be required, but arrange the arrival on the ground of the different portions so that there will be no rush at any time, but that a crew of a certain number of men, working steadily and without hurry, may perform the whole of the work. To 'rush things' is a favorite phrase with some builders, but rushing is expensive when metallurgical works are to be set up.

As a general thing, the time required for planning and building the reduction works is much underrated. It frequently happens that companies who have pursued a leisurely course of mining development, occupying perhaps years in work that could have been performed in as many months, suddenly resolve upon the erection of reduction works, and demand that they be built and put in operation hurriedly. The effect of haste in this work is invariably bad. Not only do the plans suffer, but the mechanical work is poorer and the expense far greater. I repeat with emphasis the first rule of construction, which is, *take plenty of time*. To this the reader who has read and appreciated the foregoing will add for himself the second rule, namely, *take plenty of money*.

Value of Guarantees

The ordinary guarantees by makers of machinery relate to the quality of material and workmanship furnished, and are quite conventional in words and form. There is never any difficulty in enforcing agreements of this sort, and buyers may rest secure in the quality if not in the design of whatever they may buy in the way of metallurgical apparatus. In addition to materials, some of the larger machinery houses profess to furnish advice upon metallurgical topics, especially in cases where their apparatus is about to be installed. This implies a responsibility not only as to the character of the machinery fur-

nished, but also as to the process or method of treatment to be adopted. Hence it may properly be nominated in the bond that the process and the arrangement of plant are to remain on trial until proved to be correct and advisable, and that before the dealers are paid for their wares. Otherwise their position, it is easy to see, is better than that of the professional engineer who prepares plans and gives advice for which he in the nature of things is held to strict accountability. If the machinery dealers were also held responsible for the advice they give, we should hear less unfounded boasting from them, and the condition of metallurgy would be much improved.

Value of Professional Services

The information upon which the engineer depends is furnished by maps, analyses, assays, and reports, but chiefly by personal inspection, of which nothing can take the place. No one, no matter what his qualifications may be, is justified in prescribing or planning without first having seen with his own eyes the ground of the future operations, and inspected thoroughly every part of it. This he owes both to himself and his employers. Nor can this inspection be slurred or hurried over. Time spent in such a careful reconnaissance bears excellent fruit in avoidance of mistakes, and in the improved character of the engineering. It is rare indeed that the engineer does not, with his trained vision, notice something, perhaps of great import, whose bearing on the problems in hand had not been brought to the notice of the company. Such a fact, unexpectedly developed, may result in an entire change of process; and whereas the company at first thought of putting in, let us say, a cyanidation plant, the light thrown upon the subject by the investigations of the engineer may result in the decision to use chlorination instead. Again, the original resolve may have been to use a concentrating process, in which case the recognition, on the part of the engineer, of large amounts of accessible fluxing ores previously unnoted by the projectors, has turned the scales and rendered smelting vastly more feasible.

Selection of Millsite

One of the most important duties which can fall to the lot of the engineer is the selection of the site upon which the works are destined to be built, and into the choice of which go a great deal of the experience and skill which he should possess. Chief among the considerations which govern the choice are those relating to the transportation of the ore from the mine to the works. The perpetual problem is how most cheaply to get the ore and other materials to the works, and how to get the products away. As a rule, the question deals with the relative merits of railways, overhead trams, and wagon-roads, according to circumstances. By no means can one solve these questions off-hand; but the engineer must prepare himself with such aids as contour maps, drawings, and estimates of cost, which embrace facts that cannot otherwise be taken into account. In order to know accurately the ground upon which he stands, the surveyor's aid must be in-

voked, and a thoroughly reliable contour map made, embracing all the debatable ground. The 5-ft. contours should be used, and the scale must not be cramped. On this map proceed to lay out, first, the transportation lines, particularly if railways are to be a part of the plan, and next, the actual location of the works themselves. Notice that it is important to begin with the railway. Almost all such works nowadays are connected with them, and it needs no argument to prove the desirability of so arranging matters with reference to the different departments of the works that the handling of freight of all kinds will be facilitated to the utmost. This requires that the tracks be put down first. Herein may be noted the additional advantage that they may be used both in the erection and for the repair of the works themselves. In case that wagon-roads or overhead tramways be used for the means of transport, the necessity of their prior location is less obvious, but even then it will be found profitable to lay them out in advance of other constructions.

Handling Material

The ideal method of handling materials about the works is by means of railways of the standard gage of 4 ft. 8½ in. By the exercise of skill and judgment on the part of the designer, all the requirements of freighting may be met by lines of this sort, penetrating to all parts of the establishment, whatever be its extent, and delivering all the materials wheresoever they may be required. A narrower gage may answer, but not if connecting lines are of the standard gage. Good engineering demands that such lines should be laid out with extreme care in order to obtain the utmost benefit. The sharpest curve should not be of less than 200 ft. radius, and there should be no grades whatever within the works, while if such are deemed advisable on the outside, they must slope away from and not toward the works, thus preventing damage by runaway cars and engines. Metallurgists should take care to follow the practice of the railway engineers in all this, not only as to the construction of the line itself, but also as to the character of the rolling stock which may be intended for use. Given a broad-gage road, it would be quite inadvisable to introduce miniature cars or locomotives, because by so doing would be forfeited the numerous advantages that flow from full-sized apparatus. The extreme advantages of the full-sized railway equipment are not appreciated or understood except by the regular transportation companies, who, as is well known, are always seeking to increase the size and weight of their engines and cars. This touches a principle that is universal throughout the whole domain of metallurgy. The superior economy of large furnaces, heavy stamps, powerful engines, and, generally, of the most powerful and heavy apparatus of all kinds, within the limits of practicability, are undeniable. What the extreme limits in size of practicable apparatus may ultimately be found to be is not material to the question. For the present the tendency is toward increased sizes of machinery in every branch of metallurgy. This tendency is accompanied by

another not less strongly marked tendency toward increased speed of driving. Whereas, in times not remote, and within the memory of persons still in active practice, stamps, for instance, weighed 700 lb. and fell 80 times per minute; they now have reached double the weight and drop 100 times per minute. Instances might easily be multiplied. The case of the reverberatory smelting furnaces, which have increased from 16 to 100 ft. in length of hearth, may be cited; the iron furnaces of Pittsburgh, whose internal capacity is ten times what it once was; the matting furnaces of Butte, whose capacity has increased twentyfold in 20 years, are further illustrations. In all this the principle is the same; that is to say, the economy of metallurgical devices depends, among other things, upon the size of those devices.

The designer should take plenty of room. The works, however limited in capacity, should not be cramped. Compactness, upon which many builders pride themselves, is not a merit in metallurgical plans, but, on the contrary, is a chief cause of blundering. The likelihood of future enlargements must always be faced, and the question of fire insurance is generally a live one. It might be supposed that the matter of cheap and rapid transit through the works would be favored by compactness of plant; but this is not always the case, inasmuch as it debars the engineer from the employment of the most rapid and economical means of transit when the different parts of the plant are huddled into a mass. Experience shows that the separation of large or moderate-sized plants into departments has an excellent effect upon the success of the establishment as a whole, and should always be practised in laying out new works. All necessary study should be bestowed upon the plans while they are forming, there being no economy in hurrying this part of the work. The general drawings of the works should be finished and blueprinted before a single article is ordered, or a single shovelful of earth excavated. The site must be selected, and the location of all parts of the plant, including the corners of the buildings, staked out, if the fullest measure of economy in construction and running is to be achieved. It is well known that where these indispensable preliminaries are neglected the plant costs much more, especially in the two items of grading and excavating.

Arrangement of the Plant

Little is gained in general by extensive excavation, especially if it be in hard ground, since the improved methods of elevating and transporting render it in a measure unnecessary. The ideal metallurgical works should be so arranged that all parts may be accessible by the broad-gage railway line. This necessitates laying out the plant alongside of the tracks, which must have been previously staked, with the longer axis of the buildings parallel to the rails, and not transverse, whereby the greatest convenience in the matter of dumping room is secured. The plant, if at all extensive or complicated, should be divided into departments or sections, so as to have good ventilation with freedom of each section from the smoke, gases, and flying particles

from the others. By this disposition, the cost of buildings, and particularly of grading and of retaining walls, may be much diminished. Where, on the contrary, the different parts of a plant are huddled together, not only is the cost of working greater, but that of subsequent additions to the works will also be greater. Further, the very compactness of a plant, which is so much valued by some designers, will invariably prevent the orderly and logical additions of parts that may be subsequently found necessary.

Most metallurgical works are built upon side-hills in order to get the benefit of gravitation, by which the substances undergoing treatment are assisted on their way. The practice of so building the works has become fixed by the habit of generations and centuries, and with some builders has become almost second nature. But with the improvement in machinery, by which a wealth of appliances for hoisting, transferring, and lowering the heavy and bulky materials of metallurgy now available, the arguments and reasons that formerly led to the side-hill have in good part lost their force, and a rival school, advocates of the so-called level site, has appeared. Their arguments relate chiefly to smelting, but have an important bearing upon other metallurgical processes.

Sidehill v. Single-Level Sites

A sloping or side-hill site is made up virtually of a number of terraces, upon each of which some part of the plant is placed; there may be two, three, or more of these terraces, the result of excavation into the side-hill. The single level site, which ostensibly is composed of but one level, virtually has quite as many, if by level is meant the elevation on which work is performed. For there must be, first, a lower dumping ground (called dump for short) on which the waste is deposited, and also several floors of greater or less extent, upon which the men stand to work at their tasks. Each of these floors may be entitled 'levels' with as much propriety as if they were the generally more extensive areas embraced in the side-hill site. Thus there must be a space about the head as well as the base of cupola furnaces for their proper working; the use of ore-bins implies at least two levels; and so for the usual arrangements of metallurgical works of all kinds. The conflict of opinion as regards one-level versus terraced sites was largely based upon a misapprehension, and there is really not such a great difference between the two opposed plans of construction as has been generally imagined. The greater differences arise from the method of supporting the levels (floors) and their relative positions about the works. In the side-hill plan they are laid out in an orderly sequence from top to bottom; while in the one-level plan they are scattered about the terrace according to convenience or the views of the designer. In the former they rest upon the solid or filled ground; in the other they are supported, for the most part, on framework of wood or metal. The question, therefore, is narrowed down to a consideration of the relative advantages of floors or levels supported by posts, or by earth or stonework.

It is necessary to consider the matter of installing and using the different classes of elevating and transferring machinery made advisable by the one or the other plan, together with the possibility of future enlargements and alterations—a matter that should always be kept in mind.

One-Level Site

There is no question but that the one-level site, with buildings somewhat widely separated, is the most favorable to enlargements; and while the question of convenience and economy of working is to be settled by the engineer on the spot, I am firmly convinced of the superior advantages of the one-level plant in those respects also. Doubtless, most builders will agree that ventilation is better, and that as a general thing the danger from the spread of fire is less. As a rule, there is greater economy of space in the one-level plan, as the room directly beneath the upper floors is not wholly occupied by the supports, and because the stowage spaces can be better utilized. Ore, for example, which it would be out of the question to transfer for storage from one level to another, may be moved on the same level to wherever convenience may dictate. Thus any given space on the terrace may be used successively for several purposes, while on the side-hill plan the engineer is rigidly held to one use for one space.

In the case of stamp-milling, where the course of the ore is constantly downward, and where there are no materials of any moment that require to be returned from lower to higher levels, there is little opportunity to argue against the side-hill construction. But in processes like cyanidation, where the relevation of the liquids forms an important part of the process, and which cannot be obviated, there is less reason for seeking a site upon sloping ground, as the pumping of the liquids from tank to tank cannot be much forwarded by differences of levels between the tanks.

Modern Iron and Steel Works

In the larger iron and steel works, where the quantity of material to be handled reaches its maximum, and the metallurgical engineering has advanced to a perfect appreciation of the conditions, the works are invariably, of late years, placed on level ground, with abundant room for expansion and for the application of those approved means of transport that have attained such perfection in that work. There is no question there as to the proper site to be selected, other than as influenced by the favorable conjunction of lines of transportation, and the practicable nature of the foundations, which is vastly important to their ponderous apparatus. Thus at the Phoenixhütte in Germany, and the Lackawanna works in our own country, millions were spent in the preparation of the unfortunately situated ground upon which the designers were seemingly forced to build. Fault may not be found with the selection of these sites, but it is unfortunately true that an undue amount of money is almost always put into such constructions as piling, filling, grading, and draining unsuitable ground; an expense which the merest change in transporta-

tion lines frequently renders wholly useless. If one-half the perspicuity that is devoted to the subject of metallurgical processes could be occasionally given to the study of railway or water transport, one-half the reduction plants would never be built where they are.

Necessity of Several Levels

Although the huge steel and iron plants of the day are regarded as the best exponents of the one-level plan of construction, the curious visitor will notice about them ample evidence of the universality of the many-level idea. He will observe a strict adherence to the custom of erecting the big furnaces on a platform of masonry, elevated some eight or ten feet above the general level of the works, designed very properly as the railway level. This is in order to admit of the use of the large slag and metal pots and ladles, which often have a capacity of 20 or more tons, and being mounted on wheels, and drawn by a small locomotive, transport their contents wherever required. This mode of transport renders it a matter of small moment that the slag dump may be at a distance, often of several miles. But although the dump may be so far away, it must still be a dump; that is to say, the slag must eventually be brought to repose on a lower level than the tracks. Since work is performed upon the top of the masonry platform, that also constitutes another level. Again, the top of the furnace, being the scene of more or less labor, forms a fourth level; and so on. In taking the pig iron to the bessemer vessels, a locomotive is sometimes used, which with its train of several ladles is hoisted bodily from the railway level to a position so elevated that the contents of the ladles may be poured directly into the converters. This, then, involves another level still. It can be seen after some reflection that the terrace or side-hill system of laying out these works would not answer in such instances.

Concentrating Works

In the case of concentrating works, I have always considered it doubtful if the advantages of gravity were not more than counterbalanced by the costs and inconveniences inherent in the form of construction which is now uniformly adopted. It would seem important to do away with the heavy and oftentimes costly retaining walls which this type usually requires; with the expensive and sometimes unsatisfactory wooden piers upon which rock-breakers and other heavy machinery is generally supported far above solid ground; and with the massive buildings whose frames support the shafting by which power is transmitted to the various mechanisms of such a works. Since the elevating and reëlevating of the crushed material, often to considerable heights, is an unavoidable feature of this form of ore reduction, may it not prove to be the part of economy to extend the elevating system to such an extent as to allow the crushing apparatus, the shafting, and such other parts as require exceptionally firm foundations, to rest upon the ground? Were this done, much money could be saved, particularly in the cost of the buildings, which might

be made much lighter, with large incidental reductions in the danger from fire, the cost of insurance, and in replacements and repairs.

The design and location of smelting works especially have been much modified by the improvements in hoisting and carrying machinery during recent years. Formerly, when the muscular strength of man was depended on for the transportation of the ore to the furnaces, and the removal of slag and metal, and when the daily tonnage treated did not make such a grand figure, it was almost a matter of course that the work was arranged so that the slag dump was close to one side of the furnaces, while the ore dumps were as near to the other. The hauling of slag in two-wheeled hand pots is still practised in some works, even of comparatively modern build, while the wheeling of ore from the heaps to the feeding-floors is also common. The excursion of the hand-pushed slag-pot with its 300 or 400 lb. of slag between furnace and slag dump is being replaced by the locomotive with its huge tipping basin of fifty or one hundred times that capacity; or by the granulating stream, whose capacity has never been measured.

Effects of Gravity

The effects of gravity are many and indispensable in all metallurgical operations; yet it is easy to go too far in soliciting its aid. Under an exaggerated idea of its usefulness, designers have been known to seek sites on distant hills, and to lay railway tracks for many miles in order to obtain the advantages of a drop of some few feet. These advantages are measurable, if at all, in terms of the cost of elevating the same materials an equal distance by mechanical means. If the cost of doing this by such means commonly used be considered, an approximate idea of what such a drop is worth in dollars and cents will be gained, and many would doubtless be surprised at its small value. The actual cost of the power for raising weights is but a trifle. The power of one horse, as is well known, is sufficient to raise 33,000 lb. one foot per minute, at which rate he could in 24 hours elevate the whole of the material consumed in a thousand-ton smelter a distance of 22 ft., which is not far from the average height of a copper or lead blast-furnace. If an allowance of 50% be made for losses from the inefficiency of elevating and hoisting machinery, and assume that the horse be replaced by electrical or steam power at an expense of \$50 per year, the daily cost of the power for elevating the above amount works out to 28c. Other elements which enter into such an estimate, such as the cost of attendance, repairs, and in particular the loss by interruption of the work, modify it considerably, although the result will always show the impolicy of going far to secure the assumed advantages of gravity. Further, the engineer should not lose sight of the fact that some means are always necessary to raise the ore and other materials to the summit of whatever eminence is to be chosen, this possibly involving the use of an extended line of railway, whose use would not commonly be thought of as pertaining to the reduction plant and process.

Stoping Methods in Michigan Mines

By P. B. McDONALD

The choice of a mining method for an undeveloped property is a matter which should receive careful attention, as it involves a problem of prime importance in the economic working of the property. As the supply of cheap timber has decreased during the past 20 years, making the square-set method of mining expensive, a wide variety of new methods has been advanced, each particularly suited to certain local conditions. The object of the new methods has been to do away with the use of so much timber and to make mining safer, thus reducing the loss of life. The notable increase in the mining of large,

The caving system is usually not suitable to a small or medium width orebody, but is a cheap mining method for a large massive deposit. At the Tobin iron mine of Corrigan, McKinney & Co. at Crystal Falls, Michigan, block caving is employed. A sub-level is opened 25 ft. above the main level, and a checkerboard of drifts and cross-cuts is driven on this sub-level, making a number of short vertical pillars in the ore, which are reduced to suitable size and then all blasted at once, thus undercutting a great block of ore 100 ft. high. As the ore slowly caves it racks and grinds itself into small pieces con-

FIG. 1. BACK-STOPING.

FIG. 2. DRY-WALL METHOD.

irregular shaped, low-grade orebodies has been a favorable factor for the development of new methods, mainly because an efficient mining method is a necessity in the mining of low-grade ore. In most of the recent methods, shoveling of ore in the stopes is avoided as much as possible, on account of the high cost of this work. There are several mines paying dividends today that were failures before a system of mining was evolved which suited the local conditions at each property.

Classification of Mining Methods

Mining methods are usually classified as to whether the stoping is overhead or underhand or a combination of the two, but there is a better classification having to do with the condition of the stope itself. The stope may be open, as in relatively narrow veins of hard ore, with very little or no timber used in the process; the stope may be kept filled with broken ore or waste rock on which the miners stand to drill; or the caving principle may be employed in which a block of ore is undercut and part of it removed, the balance being allowed to settle due to the force of gravity.

venient for loading into tram cars and is subsequently discharged through chute-raises to the main haulage level and trammed to the shaft. The ore at this property is a medium hard, red hematite.

Pewabic Mine

In the Pewabic mine at Iron Mountain no sub-level is driven, but blocks of ore 250 by 200 by 100 ft. high are caved into the main level where pillars 8 ft. square have been shot out. The block of ore is first undercut along the foot-wall and one end. When the pillars have been withdrawn the ore gradually settles to the floor, and in spite of the fact that it is rather hard ore, it is crushed so that 80% of it can be put through a 3-in. opening. This caving process takes from 6 to 8 months. Timbered drifts and cross-cuts are then driven through the crushed ore, and the trammers shovel the ore into cars, beginning at the more remote headings, and pull down the timber sets as they retreat. The cost of mining by this method at the Pewabic is about 50c. per ton. It will be noted that the cost of explosives and timber are naturally low. It need scarcely be stated that caving methods of mining

render the overlying surface unfit for buildings, railroads, and the like.

On the Mesabi range in Minnesota caving methods suitable to soft ores are extensively used for mining large flat lenses of iron ore. On the Mesabi, and in some parts of Michigan, caving is accomplished in sub-levels by drawing horizontal slices 8 to 20 ft. high and extracting these successively from the top downward. The overlying rock or sand caves and is kept separated from the ore by a mat of timber and lagging; this overlying material furnishes weight which helps cave the few feet of ore over the 'room,' which is 8 ft. high, and is excavated by the miners underneath the block to be caved. Caving in horizontal slices by means of timbered sub-levels is a more careful method than the block-caving methods used at the Tobin and Pewabic, but is also more expensive in labor and timber and is better fitted for a high-grade ore. It is necessary to

The levels are usually 100 ft. apart; when the stope is within about 20 ft. of the level above, the unbroken material is left as a floor pillar as long as it is desired to maintain the level above, after which this floor pillar is drawn retracting toward the shaft. This method of mining is especially suitable for a steeply dipping vein from 8 to 12 ft. wide. It has been successfully used in the hard ore mines of the Michigan iron regions. Some operators object to mining on broken ore, because of the capital represented in the large amount of broken ore which is necessary for keeping the stopes filled.

Dry-Wall Method

Fig. 2 shows the main features of the 'dry-wall' method used in some of the South Range copper mines of Michigan where the dip is sufficiently steep. The main haulage drift is driven lengthwise of the lode and is widened out to the full width of the ore-

FIG. 3. OPEN-STOPE METHOD.

shovel practically all of the broken ore, and nearly all the drifts and 'rooms' have to be carefully timbered. The 'caving' is not caused by removing the pillars, but by widening the timbered room 8 ft. high and caving the few feet of ore overhead. In some cases the slices are only 8 ft. thick altogether, so that practically none of the ore is caved. The term caving applies principally to the overlying rock and sand.

Back Stopping

Fig. 1 illustrates back stopping. By this method the stope is kept nearly full of broken ore upon which the miners stand when drilling into the back. The broken ore is removed by trammers on the haulage level by prying apart the cross-lagging over their heads and letting the ore drop into the tram cars. The cross-lagging rests upon timbers laid lengthwise of the drift, which in turn are supported by heavy timbers placed at intervals across the drift with their ends securely recessed in the walls. The miners climb to the back through ladder-ways or raises which are left at intervals. The level of the broken ore may be kept on a slope lengthwise of the orebody so that flat stope holes may be drilled and the ore broken in benches; or the broken ore may be kept horizontal and 'uppers' drilled into the back.

body, perhaps 20 ft., by 'breast-stopping.' The broken material is carefully sorted and the waste rock is built into 'dry-walls' (so called because no mortar is used) on each side of the track, perhaps 8 ft. apart. The miners are very skillful at building these dry-falls, and the finished walls, which are 7 ft. high, are surprisingly straight and solid. The balance of the waste-rock is thrown behind the dry-walls. Heavy timbers are now laid across the drift, the ends resting on top of the dry-walls; these timbers are spaced at about 2-ft. intervals and planks or timber are laid on them lengthwise of the drift, thus making a tight roof to the haulage way. Overhand stopping is now started, the miners standing on this platform and using it as a floor. As the stopping progresses, the broken material is sorted and the waste rock is kept to stand on, while the ore is thrown down chutes to the haulage levels. The chutes are built in the waste rock by the dry-wall method of stone laying, and are about 65 ft. from centre to centre. If there is not enough waste rock to make sufficient fill to stand on, a raise is driven to the level above or to the surface, and broken filling is run into the stope until the men can stand on the waste and reach the back for drilling. The top of the fill is usually kept level and small cars may be used on it for handling the ore. If it is desired

to use horizontal holes to break the ore, a portion of the fill may be kept at an angle of about 40°, upon which the miners can stand and drill and thus break the ore in benches; otherwise 'uppers' are used. This method of mining is obviously suited for ore that requires considerable sorting, and gives better results than going to the expense of hoisting all the broken material to the surface before sorting it. Native copper rock is easy to sort, especially when the surfaces are fresh, as is the case immediately after blasting. This method of mining is also

mining methods, the floor pillar can be drawn, retreating toward the shaft, when desired. Workings left for a long time are apt to get dangerous. This method of mining is suitable to mines where a small daily tonnage is hoisted and where it is desired to obviate dead work and tying up capital. Where the ore is variable and pockety, this method is especially suitable, as the poor material can be readily left as pillars in the mine. Some mines leave 40% of the vein material unbroken because of its poor showing; incidentally these pillars tend to make the workings

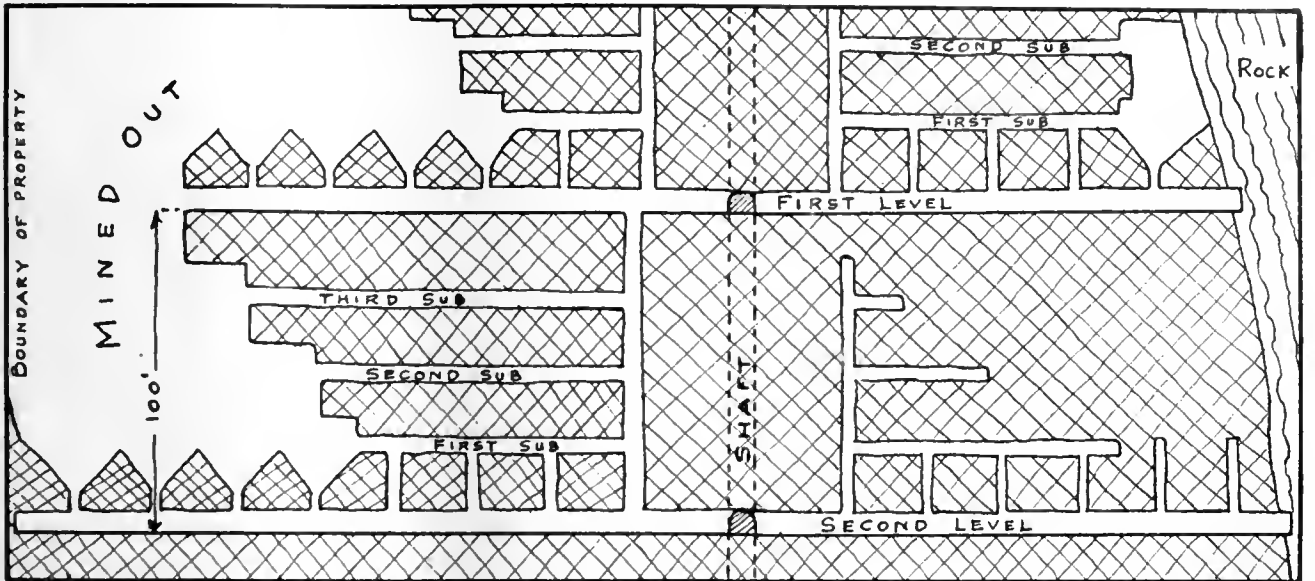

FIG. 4. SUB-LEVEL STOPING METHOD.

safe, because the miners can watch the roof over their heads and see in advance any signs of caving. The cost of mining is usually over \$1 per ton, but this refers of course to the sorted product which is the result of careful underground sorting, and should not be directly compared to a method which hoists both ore and waste before sorting.

Open-Stope Method

Fig. 3 shows an open stope method of mining which is used in various parts of the country with orebodies up to 30 ft. in width. This method is simple, makes little 'dead' work and permits ore being stoped almost as soon as the shaft is sunk. It has the disadvantage of a high roof over the trammers' heads, which is dangerous in mining soft ores. The shaft may be sunk in the ore following the dip of the vein (as in sketch), or it may be a few feet back in the foot-wall and maintain a constant dip. Levels are usually 50 ft. apart measured along the dip. The drifts are kept small near the shaft, but, after leaving a suitable shaft pillar, a stope is opened about 30 ft. high. When the system is well started, driving along the vein takes place near the roof of the stope in what is called the 'heading,' this drift being later widened to the full width of the orebody. Stope holes are put in on the slope leading from the haulage level up to the heading; both down-holes and 'lifters' can be used, and when blasted they break the ore in large masses and chunks that may need sledging to handle conveniently. The roof is kept well trimmed or 'sealed,' ladders being used to occasionally inspect the older workings. As in other

safer. The cost of mining by this method is usually less than \$1 per ton.

Sub-Level Methods

Fig. 4 shows the comparatively new sub-level stoping method in use in many of the smaller Michigan iron mines with ore of medium hardness in steeply pitching, tabular orebodies up to 100 ft. in width. A vertical shaft is sunk in the foot-wall and a cross-cut is driven on each 100-ft. level to the ore, where a main haulage drift is driven in each direction, lengthwise of the deposit. If the orebody is wide, two parallel haulage drifts are sometimes driven and connected at intervals, making a convenient track system for motor haulage. Chute raises are then driven 25 ft. above the floor and spaced 25 ft. centre to centre, being put in the cross-cuts if necessary. Main haulage levels are usually 100 ft. apart; and three sub-levels are driven, spaced about 25 ft. from floor to floor. The first sub-level (consisting usually of a single drift) intercepts the tops of the chute-raises. The sub-level drifts are hastily driven and do not resemble the carefully trimmed haulage drifts. Stoping is started on the first sub-level by putting in down-holes around the end chute-raise for blasting out a funnel shaped top, 'uppers' being blasted next. The right-hand portion of the first level shown in Fig. 4 illustrates the starting of a stope, and below on the second level is shown an earlier stage of development with sub-levels partly driven. The second level on the left-hand side shows a stope well started, while above on the first level the stope is well advanced and the

floor pillar is being mined and is falling into the second-level chute-raises (thus connecting the first-level stope with the second-level stope). As the sub-levels are drawn back toward the shaft or toward the ladderway, both 'down' and 'upper' holes are used, as well as horizontal holes for widening to the walls. The walls should be firm so as not to cave and mix with the broken ore. The miners take care to keep the bottom sub-level back under the middle sub, and the middle sub-level farther back than the upper sub-level so they are protected by the unbroken ore over their heads from falls of ground in the stopes. The open stopes are of course dangerous places to enter, and no one is allowed in them. The sub-level stoping method of mining is notably a safe one, as the miners attack the ore in the stopes taken from the sub-levels where they are practically as safe as in the main haulage ways. The chute-raises are equipped on the haulage levels with ordinary wooden lip chutes for loading tram cars; by raising the planks from the mouth of a chute the ore runs out, but occasionally blocks itself from some large chunk becoming wedged, in which case a stick of dynamite may be necessary to loosen the ore.

Mining Wide Orebodies

When the orebody is wider, the mining of the ore in the sub-levels is accomplished by maintaining a bench to the wall on each side which gives the miners a place to stand; the middle portion of the ore (where the sub-level drift is) is kept drawn back ahead of the sides, giving a semi-circular effect to the edge of the stope. In some cases where the sub-levels are rather far apart vertically, all the ore between cannot be reached either by the uppers from below or by one set of down holes from above; it is then necessary to climb down from the upper sub-level to the bench remaining, when the first set of down holes was blasted, and drill another set of down holes. Should the ore be too soft to permit this bench to hold a man and a rock-drill, it would be necessary to space the subs nearer together and have more of them. The expense of driving the sub-levels is one of the disadvantages of the method. Where the orebody is long, it is customary to make the stopes about 250 ft. in length, separating them by ladder-ways protected by vertical pillars. It will be noted that this method of mining is an open stope method, in that the stopes are not filled with broken ore, waste, or caved material. The method has been adopted by mines that in the old days would probably have used the square-set timber method, and is sometimes preferred to the method of back stoping on broken ore.

The four methods of mining just described are applicable to steeply dipping orebodies. When the vein has a shallow dip, say 20 to 40°, it is usually much easier to devise a cheap mining method, because the miners can then stand on the foot-wall as they work up from one level to the next. It is possible to drive the main haulage drifts to the property boundaries and commence stoping in a retreating system, holding the hanging wall by pillars or timbers so long as mining is in progress on that level. The Wolverine copper mine in Michigan has had a

notably low mining cost, partly because of the shallow dip of the lode, which makes mining comparatively simple. In early days in the Lake Superior district miners tried to hold up the hanging wall indefinitely by timber stulls, which was impossible below very shallow depths. In some of the older stopes of the Calumet & Hecla mines, timbers once 10 or 15 ft. high can be seen which have been crushed down to 2 or 3 ft. by the slowly sinking hanging wall. It has been recognized that, since the hanging wall cannot be held up, it is better to devise methods which allow the hanging wall to come down, timber being used only for local purposes to prevent falls of ground.

Imports of Potash Salts

The importation of potash salts for consumption in the United States during 1912 amounted to 622,179,164 lb., valued at \$10,692,285, according to W. C. Phalen, of the U. S. Geological Survey. This importation is only a part, however, of the potash salts entering the United States. To it should be added the importation of kainite and manure salts, including double manure salts. The imports of potash salts of these classes amounted to nearly 700,000 long tons, valued at more than \$4,000,000. The imports for consumption of materials entering largely into the fertilizing industry, plus the domestic phosphate rock, reached the total valuation of over \$46,000,000. These statistics in detail, together with others showing the condition of the German potash and salt industry, are given in the Survey's report on potash just issued as an advance chapter of the volume 'Mineral Resources of the United States for 1912.'

The investigations of the Geological Survey in 1912 into sources of potash salts in the United States included a continuation of deep drilling in Nevada, begun in 1911; a continuation of the collection of samples of rock-salt brines and bitterns, and of the study of the salt industry of the United States; the examination of various dried or partly dried lakes, *playas*, flats, or marshes in several of the Western states, both within and without the Great Basin, including Arizona, California, Nevada, New Mexico, and Nebraska; the investigation of deposits of potassium nitrate in California and Montana; and the investigation of occurrences of alunite in Arizona, Colorado, and Nevada. Information on all these investigations has either been published or is in process of publication by the Survey.

Mr. Phalen's report contains abstracts of papers on sources of potash published by the Bureau of Soils and by private individuals during 1912, as well as sections on potash salts as a by-product in the manufacture of portland cement, and on the utilization of kelp at Cardiff and Terminal Island, California.

Anthracite production of Pennsylvania in 1912 totaled 75,322,855 tons, valued at \$177,622,626, against 80,771,488 tons, and \$174,952,415 in 1911. There were 174,030 men employed, who worked an average of 231 days during the past year.

Equipment at the Crown Mines

*The paper on 'Centralized Organization at the Crown Mines,' which was read by R. C. Warriner, the general manager, before a recent meeting of the South African Association of Engineers, is the most complete that has ever been prepared to describe and illustrate the main features of the ore-handling operations of a mine upon the Rand. The following extracts are of special interest.

Sorting and Crushing Station

At No. 5 shaft the ore is delivered from the skips to the grizzlies at the head-frame which consist of two sets; the upper set is spaced 3¾ in. and 8 in. apart, and lies at an angle of 22°. This upper set was put in, firstly to take the shock of the falling rock from the 'fines' grizzly, and secondly to retard the flow and so obtain better grading. The second set or 'fines' grizzly is spaced 2 in. apart, and lies at an angle of 45°. The grizzlies are placed immediately above the 'fines' bin, and the 'fines' accumulated in this bin are loaded direct into the 50-ton hopper trucks for transport to the mills. The oversize from both sets of grizzlies is delivered into a coarse-rock bin, whence it is fed to the sorting belts. The ore is washed as it is fed to the sorting belts in a chute fitted with sprays, and having a bottom fitted with grizzlies of fire-bar section to remove the coarse particles, slime, and water. The washing water for these sprays is delivered from a 5-in. Enke high-lift centrifugal pump, which is supplied from the mine pump column. The washing water is run by launder to a revolving separating screen which removes all particles over ¼-in. size. It then runs to an 8-in. Robeson-Davidson sand pump, which delivers it to a conical separator at 'C' mill, the overflow going direct to the slime-collecting tanks and the underflow to tailing pumps, and then to tube-mills. The oversize from the separating screen is delivered into a small concrete bin from which it is raised periodically by means of a small air winch and skip, and tipped into the 'fines' bin at the head-frame. By this method clean water is used for washing, the labor usually employed for cleaning settling sumps is saved, and other difficulties common to this portion of a sorting station are overcome.

Sorting Belts

The sorting belts, four in number, are 36 in. wide, have an inclination of 14°, and are run at a speed of 150 ft. per minute. Each belt is driven by a 25-hp. motor, running at 500 r.p.m. through a 60-to-1 reduction gear, fixed between the head pulley of the sorting belt and the pulley driven from the motor. To this pulley is attached a 'Benn' friction clutch running in oil, and by this means the belts are stopped and started at will. This system is to provide for the thorough sorting of each portion of the belt. For example, a belt loaded with rock from the bin is run out and stopped. It is then the duty of each boy to pick the belt clean of waste immediately in front of him. As soon as the over-

seer in charge is satisfied that all the waste has been removed, he places a chalk mark at the bottom end of the belt, which is then set in motion and stopped again when the above-mentioned chalk mark is opposite the foremost sorting-boy. The waste sorted is placed on the under side of the belt and is delivered into a waste-rock bin of large capacity. One boy is employed on each waste-rock belt sorting out any 'reef' which may have been accidentally discarded. The waste is loaded from the bin into 20-cu. ft. side-tipping cars, and these cars are elevated to the level of the top of the waste dump by a creeper chain-gear, the capacity of which is 6 tons per minute. This chain ascends an incline of 20° at a speed of 60 ft. per minute. The system has proved most satisfactory, a considerable saving of labor being effected when compared with other types of elevators, and this is the first plant at which it has been installed on these fields. At the head of the creeper chain-gear, the cars are attached to a mechanical haulage which conveys them to the dumping point.

Tube-Mill Pebbles

During the sorting operations, tube-mill pebbles are also picked and deposited on a conveyor belt running diagonally across and under the sorting-floor in such a manner that the pebbles can be picked from either of the four sorting belts. The pebble conveyor delivers into a partitioned-off portion of the main bin under the crushers, from which the pebbles are loaded into the 50-ton hopper-shaped cars for transport to the tube-mill pebble bins at the various mills. The sorted ore is delivered at the upper end of the sorting belts into a distribution box or bin, which feeds three 12 by 30-in. Hadfield & Jaek reciprocating jaw crushers, for reduction to 1½-in. diameter. The crushed ore falls directly into the main ore-bin and is loaded from there by pneumatically operated doors into the 50-ton hopper trucks. The whole of the plant is electrically driven by separate motors for each piece of machinery, the crusher motors being 60 hp. each. The crusher station and bins are built of ferro-concrete, and the sorting station of steel. The plant was laid out for a crushing capacity of 6000 tons in 10 hours, but for individual hours the output has been as high as 750 tons. The following table showing units of power consumed and cost of same for crushing and sorting should prove of interest:

Month.	Tons hoisted	Crushing.			Sorting.		
		Total units consumed	Units per ton	Cost per ton, pence.	Total units consumed	Units per ton	Cost per ton, pence.
October	105,836	26,195	0.25	0.13	13,500	0.13	0.07
November . . .	101,896	35,431	0.35	0.18	17,500	0.17	0.09
December . . .	109,430	29,444	0.27	0.14	23,500	0.22	0.12
January	135,940	27,675	0.20	0.11	29,500	0.22	0.12

Between 400 and 500 miles of 6, 8, and 10-in. pipe is being made by the National Tube Co., of Pittsburgh, for oilfields in Rumania, Europe.

*Abstract from *South African Mining Journal*.

The Mineral Resources of Virginia—III

By THOMAS LEONARD WATSON

Virginia has more known deposits of manganese and has produced more manganese than any other state in the Union. Manganese ores occur in each of the three major geologic provinces of the state, namely, the Coastal Plain, the Piedmont province, and the Appalachian Mountains province. Of these, the Mountain province has yielded the principal production, with extensive operations and a large total production from the Piedmont province. Only a small production has come from the eastern or Coastal Plain province. The beginning of manganese mining in Virginia and perhaps in the United States was in 1857, when 100 tons of ore was reported taken from the lands of Joshua Robertson about five miles from Waynesboro, Augusta county. The principal productive manganese deposits in the state are: (1) those of the Piedmont region occurring chiefly in Campbell and Nelson counties, south and northeast of Lynchburg; and (2) those of the Valley region occurring along the west slope of the Blue Ridge.

Only the oxides of manganese are of commercial importance in Virginia. Of these, pyrolusite and psilomelane greatly predominate with, in places, much of the earthy oxide, wad. These oxides often occur admixed in varying proportions. The ore is often partly or entirely crystalline, of a dark steel-blue color, and the nodular (kidney) type, which usually prevails, often displays a complete or partly layered structure.

Ores of Manganese

The manganese ores are usually found imbedded in the residual clays which overlie the rocks, from which the clays have been derived by the usual processes of decay. The underlying rock yielding the ore-bearing clays may be of sedimentary or igneous origin. The ore is distributed in clays in an irregular manner in the form of pockets or lenticular masses, rarely as distinct beds; as veinlets and stringers cutting the clays in all directions; as single nodules and masses, ranging in weight up to 500 pounds, assembled in the clays; as small disseminated grains scattered through the clays; as breccia ore in large masses; and as probable replacement and cavity fillings in sandstone or sandy clay. In places, both in the Piedmont and Valley regions, the ore distribution conforms in a general way to the bedding of the inclosing clays; frequently, however, this is obscured and the orebodies indiscriminately cut the clays in all directions.

The nature of the manganese ores mined in Virginia is one of irregular distribution, in the form of nodules and pockets, through residual clays, which range in thickness from a few feet up to several hundred feet. The method of mining depends largely upon the situation of the deposits and their depth below the surface. Open-pit and underground methods are both employed. These methods are often used to advantage in combination. Un-

derground timbering is necessary on account of the liability of caving of the clays.

Tin

Though not a producer of tin, the existence of tin ore in Virginia, in the Irish creek area of Rockbridge county, has been known for many years, and in 1883 and later the deposits were opened in several places. The Irish creek area is about four miles long in a northeast-southwest direction, and three miles wide. The tin ore (cassiterite) occurs principally in greisen veins, which traverse the granite in all directions and have steep though varying dips. The Irish creek tin area was carefully examined in 1885 by the late Jed. Hotchkiss, who concluded his report on the area as follows: "In conclusion, this report is emphasized by the opinion that this Irish creek tin-bearing district, as above described, will prove abundantly productive in tin."

Nickel and Cobalt

The existence of nickel in Virginia has been reported from a number of localities in the Piedmont region, especially in association with extensive pyrrhotite bodies of the Floyd-Carroll-Grayson counties plateau in southwest Virginia, and in Amherst county east of Lynchburg. More recently nickel has been reported from near Broad Run station in Fauquier county. In addition to the above occurrences, cobalt is found in association with some of the impure earthy manganese deposits of the Valley region, especially along the western base of the Blue Ridge. Probably the most encouraging locality from which nickel has been reported is in the northern part of Floyd county, where the Virginia Nickel Corporation has done considerable exploratory work on Flat Run and Lick Fork. The ore is chiefly pyrrhotite, with some chalcopyrite.

The rocks immediately associated with the ore are, without exception, of igneous origin, and comprise pyroxene syenite, diabase, and gabbro. These are intruded into the country schists and gneisses. The gabbro and diabase penetrate the pyroxene syenite in dike-like forms and are accordingly younger in age. The mica-gabbro is the ore-bearing rock. In some parts of the gabbro, the sulphides are sparingly present, in others they make up 50% and more of the total rock mass, with all gradations between.

Arsenic

In 1903 the United States Arsenic Mines Co., of Pittsburgh, Pennsylvania, began the mining of arsenopyrite (mispickel) at Rewald, in Floyd county. An extensive plant, erected for refining the product, was started in 1904, with a monthly capacity, after January 1905, of 90 tons of pure white arsenic. Operations were temporarily abandoned several years ago, but were resumed in 1911.

The mines are 17 miles from Christiansburg, at Rewald, Floyd county. The ore is arsenopyrite, a

double sulphide of arsenic and iron, and occurs in 'veins' (lenses) in quartz-sericite schist, which is closely associated with biotite gneiss, but the relations of the two rock types to each other, and of the gneiss to the orebodies, are unknown. The principal orebody is reported to be 3 ft. thick at the surface and widens to a thickness of 14 ft. at a depth of 120.

Rutile (Titanium)

The Virginia rutile deposits are only known rutile deposits of commercial importance in the United States. Rutile is mined in the Tye River-Hat Creek area of Nelson county. The area is a large one, situated in the foothills region of the Blue Ridge, and is about seven miles northwest of the main line of the Southern Railway. Recent detailed field studies of this area by the Virginia Geological Survey indicate practically an unlimited supply of rutile, which can be concentrated to yield a high-grade product, much of it containing more than 99% of TiO_2 . Since 1902 the Virginia deposits have supplied all the rutile used in this country, and much of the product has been shipped abroad. With the development of new uses of titanium—the two most important being in the manufacture of ferro-titanium for the production of special grades of steel, and in the manufacture of arc-lamp electrodes—and the consequent increasing demands for rutile, the prospect for the future of rutile mining in Virginia seems decidedly encouraging.

Two distinct types of rutile occur in the district, and each has been mined. In the first type, designated syenite (formerly pegmatite) rutile, the rutile occurs as disseminated grains of various sizes and as wavy lines in a coarse-grained feldspar-quartz-hornblende rock. In the second type, designated nelsonite rutile, the rutile occurs in an even-granular rock, having dike-like characters, and composed normally of ilmenite and apatite. The American Rutile Co. began mining the syenite (pegmatite) rutile in 1901 on the east side of Tye river near Roseland, and in 1902 a milling plant was built for concentrating the ore. In 1907 the General Electric Co. exploited the nelsonite dikes, near Rose's Mill, for rutile.

A second area of rutile has recently been discovered in Goochland and Hanover counties, Virginia. The area is an encouraging one, and some prospecting work has been done near Peers in Goochland county, and near Waldelock and Gouldin in Hanover county. The rutile is found as an original constituent in acid pegmatite dikes which penetrate gneisses derived from granites by metamorphism. Masses of nearly pure metal weighing many pounds are found in places on the surface admixed with the residual rock decay produced by the processes of weathering.

Mica and Minor Minerals

Pegmatites containing commercial mica have been abundantly developed in many parts of the Virginia Piedmont counties, and many excellent surface indications occur. Up to the present time, however, prospecting and the mining of mica has been confined to only a few of the known deposits. Dikes

of pegmatite containing feldspar as an important constituent are quite widely distributed throughout the Virginia Piedmont region. Feldspar, with the associated mica of the pegmatites, has been mined in a number of counties. In the years previous to 1907, Virginia was a producer of asbestos, but since that time the mines have been inactive, although the mineral is known to occur in several counties. The mill for fiberizing the asbestos at Bedford City has been closed since 1906. The gypsum deposits occur associated with the salt deposits of Washington and Smyth counties, in the valley of the North Fork and Holston rivers. The date of the discovery of gypsum in Virginia was probably in the early part of the nineteenth century. The mines of the United States Gypsum Co. and the Southern Gypsum Co., which are situated northeast of Saltville, are the most extensive and the only producing ones at present.

Salt mining has been an important industry for a number of years. In 1771, Jefferson mentioned in his 'Notes on Virginia' the occurrence of salt brine in the Holston valley, but it was not until 1840 that rock salt was discovered. A large number of wells have been bored, ranging in depth from 300 to 1400 ft., the greatest depth being 2380 ft. At the present time there are about 24 producing wells. The mining of rock salt has not as yet been attempted, the entire salt product being derived from the salt brines of the wells. Of recent years the brines have been utilized exclusively for the manufacture of sodium carbonate and caustic soda. The product has been of superior merit from the start, and because of this fact a large and growing trade has been acquired.

Virginia is entitled to take rank among the chief coal-producing states. Many of the reserves have been made accessible recently through the construction of new lines of railroads. The area of the southwest Virginia coalfield is estimated to be 1550 square miles, with the original supply of coal placed at 22,500,000,000 tons, of which total but a small percentage has been mined to date.

Sulphur Industry of Sicily

There was nothing noteworthy in the trade of the year 1912, differences in exchange rates excepted, prices remained practically stationary. Shipments to Greece and Turkey showed a decline because of the Balkan and Italo-Turkish wars.

The total exports of crude and refined sulphur from the island of Sicily in 1912 amounted to 447,590 metric tons, which was a slight decline from 1911. The chief purchasers of Sicilian sulphur were as follows: France, 104,109 tons; Italy, 77,396 tons; Austria, 38,359 tons; Norway and Sweden, 34,850 tons; Germany, 32,286 tons; Russia, 25,562 tons; England and Malta, 19,833 tons; Australia, 11,285 tons; and United States and Canada, 2894 tons. Prices averaged, refined, \$20.94 per ton; refined-ground, \$23.16; refined-rolled, \$21.80; and sublimed, \$26.63 per ton. The production was 357,547 metric tons; and stocks at the end of 1912 were 450,917 tons.—*Consular Report*.

St. Joseph Lead Company

By DWIGHT A. JONES

*The production of lead from the smelter during the past year has been 66,847 tons. Of this amount, 32,109 tons was from purchased ores, 31,296 tons was produced from our own mines, and 3442 tons was from stock at Herulanenm. The average price received for lead at East St. Louis was 4.35, or approximately \$87 per ton, there being some increase in the average price for the year. The net income from all sources, after the payment of all expenses and income charges, and after setting aside \$75,626 for depreciation, was \$637,910.37 in comparison with \$598,082.52 in 1912. Dividends amounting to \$597,300 were paid during the year, being 6% on the outstanding capital stock.

Influence of Industrial Situation

In order that the stockholders may appreciate the situation that has existed with reference to the work and earnings of the Company during the last few years, it is desirable to recall the great change in the general industrial situation which occurred during and after the year 1907, as the lead industry was seriously affected by this change. In 1906 the net income was \$1,256,545.68, and in 1907 it was \$2,038,820.32. For the year 1906 the price of lead at East St. Louis was over \$100 per ton, and for the year 1907 it was over \$114 per ton. In the following year, 1908, the price dropped to \$88, and the net income fell to \$657,446.89. While the Company had, during the years preceding 1908, taken many steps to increase its output and to improve its plants, which for the most part were built many years previous, it was suddenly confronted with a situation that demanded drastic action in all its widely separated departments.

As the most essential and most beneficial possession it could have was a strong and adequate lead reserve, much time had been devoted and much money had been expended in drilling adjacent lands, so that all the deposits that were available at low cost could be secured and so that other companies would not crowd upon its territory. In doing this it was realized that only a portion of the work had been accomplished, which was necessary for broad development into a thoroughly equipped mining concern with a modern power-plant, modern mills, and a modern smelter. A new mill, then equal to the capacity of any mill in the district, had been built in a new territory and was first in complete operation in the year that ended on April 30, 1905. Notwithstanding the improvements in the mining plants which had been made, it was realized each year, with the continuance of the low price of lead that has prevailed since 1908, that mining must be done on a large scale to make the work profitable under new conditions, and must be confined to as

few mines as practicable, and that mills to be profitable in the district must also be capable of handling a very large tonnage with a minimum of loss, and that modern smelting plants must be equipped with every known method of saving lead to accomplish work economically and efficiently. On these accounts, it has been necessary for the Company to discard old power-plants, old mill methods and equipment, old roasting, smelting, and refining furnaces, and as rapidly as large mines could be found, to abandon mining from scattered shafts, which had been the necessary practice for many years.

Improvements

During this period also various improvements in mining, milling, and smelting have been introduced, and even some of the later methods have been displaced by newly patented processes, especially in the smelting department, where this Company was the first in any country to use a large-size Dwight-Lloyd sintering plant. These considerations are brought to the attention of stockholders that they may understand the conditions that have prevailed since 1908 and may appreciate the necessity for a considerable expenditure of money. It has been the aim and desire to furnish all needed improvements as soon as plans could be perfected for such improvements. This policy has been necessary, and the ample and newly discovered ore reserves made this policy wise and practicable. The pig lead product from mines owned by the Company in the year that ended on April 30, 1900, was 12,196 tons, and in 1912 was 34,195 tons. The pig lead product from the Company's smelter in 1900 was 19,270 tons, and in 1912 was 62,922 tons. The net income in 1900 was \$231,294.60, and after reaching its highest point in 1907, was in 1913 \$637,910.37, owing mainly to the reduced price of lead. Since 1899 the Leadwood district, now the main mineral reserve district, was acquired; the Hoffman, Hunt, Day, Eaton, Angel, and Prospect Lead Co. tracts, containing 1631 acres of mineral land, having been purchased from the owners. The new mill at Leadwood and the three shafts supplying it with ore, and the power-plant and other accessory plants, have been entirely constructed. Other valuable tracts of land in the Bonne Terre district have also been acquired, and, by prospect drilling, large and valuable ore deposits have been disclosed.

Financial Standing

On April 30, 1900, the Company owed \$292,319.99, after deducting its cash and bills receivable. In the period from this date until April 30, 1913, the Company expended approximately \$4,400,000 in construction essential for its increasing product and operations, and it has written off for depreciation on property and plant over \$2,500,000. No fixed amortization charge has been adopted because the value of the mines has been constantly increased by drilling, and it was not deemed advisable to

*From report as president for the year that ended on April 30, 1913. Details regarding the difficulties of this company were given in the *Mining and Scientific Press*, November 9, 1912, and March 24, 1913. At the latter time a summary of the balance-sheet for the year was printed.

take up this subject until a reasonable approximation to their full value could be made. Summarizing the entire indebtedness of the companies, it appears that the St. Joseph Lead Co. owes, less cash, notes, and accounts receivable, \$1,982,307, that the Mississippi River & Bonne Terre railway owes, less cash, notes, and accounts receivable, including its indebtedness on its equipment notes, approximately \$800,000, and that the Bonne Terre Farming & Cattle Co. owes practically nothing except its indebtedness of \$244,450 to the St. Joseph Lead Co. It is, therefore, seen that the three companies, with assets conservatively valued at approximately \$19,000,000, less cash, notes, and accounts receivable, have a total indebtedness of \$3,000,000.

Additions to the Property

The total amount paid for lands bought by the St. Joseph Lead Co. since 1899 has been approximately \$300,000. After extensive prospect drilling on properties acquired, large and valuable deposits were found. In the years 1902 and 1906 the values of the Hoffman and Hunt mines were increased on the books of the Company \$5,500,000. That these mines are even now far more valuable, recent drilling has fully proved. Moreover, since 1904, lead of a gross value of over \$15,000,000 has been taken from the property. Additional exploration has greatly extended the territory in the neighborhood of these mines.

In the entire period since its organization, the net income of the Company has been \$15,247,022, while its total cash dividends have been \$8,717,486. Many important improvements are yet under way, and it may be desirable for the Company to make still further extensions to its plant, but when the improvements now in process of completion are finished, there is likely to be a great addition to the net income, and before undertaking further expenditures it is deemed desirable to go over the whole situation with respect to the ore reserves and plants. The savings to be effected in the immediate future include those resulting from the larger stopes in the mines, the abandonment of old steam-plants, and the introduction of Hancock jigs and other modern mill machinery at Bonne Terre, and also from the mine, mill, and power improvements at Leadwood. It is also expected that from the many new and systematic methods and the recently erected large flue at Herculanum and the new bag-house now in course of construction, material savings will be effected in the smelting department.

During the years since 1908 the price of lead received by the Company at East St. Louis has been for fiscal years as follows: 1909, \$81 per ton; 1910, \$85; 1911, \$84; 1912, \$83; and 1913, \$87 per ton.

Future Outlook

A normal increase in the consumption of lead has taken place from year to year, and the great activity in electrical work, both in Europe and this country, indicates that the price will advance. During September 1912 lead in London and in New York sold at practically \$100 per ton, but has unfortunately receded for a time. In view of these considerations and of the work that has been accomplished

in securing lead reserves, and in rebuilding and re-organizing the plants and mining operations, it is believed that the stockholders will in the future find much cause for satisfaction. Such improvements as have been made on the surface lands of the company have resulted in causing an increase in the value of other real estate held by it.

Doe Run Lead Co.

The ore output of the Doe Run Lead Co. for April 1913 was over 4200 tons of lead concentrate, valued at approximately \$179,000. The business of the St. Joseph Lead Co. as a lead producer and refiner, and as the owner of an industrial railroad necessary for its own purpose, is much more valuable with the large ore and concentrate product of the Doe Run Lead Co. to handle, than without it. It is of great importance that this business should be retained and that the alliance with the Doe Run Lead Co. should be continued in some shape. The smelting contract between the St. Joseph Lead Co. and the Doe Run Lead Co. was approved by the board of directors of the St. Joseph Lead Co., and is a fair contract. In Missouri it has been criticized as unfair to the Doe Run Lead Co., while in New York it is criticized as unfair to the St. Joseph Lead Co. The contract was made for a period of 3½ years, of which period one year has already expired. It provides that the concentrates of the Doe Run Lead Co. shall be purchased at the market price, with a fixed charge of \$6 for smelting and a deduction of 10% for loss. It also contains a provision that an average price for the year of not less than 4c. shall be paid for the lead in the concentrate. The average price of lead has not been below 4c. at East St. Louis for over 12 years. The contract contains a provision allowing for the alteration of its terms.

If a consolidation of the St. Joseph Lead Co. and the Doe Run Lead Co. could be effected, there is no doubt but that a substantial reduction of expenses could be made, and that more freedom could be obtained in carrying on the joint operations of the companies. It is, therefore, to be hoped that such a consolidation can be brought about.

Large Driving Belts

Two large driving belts were recently made in San Francisco by the H. N. Cook Belting Co. for the American Beet Sugar Co., at Oxnard, Ventura county, California. Their dimensions are (1) 76 in. wide, 4 ply, by 105 ft. long; and (2) 65 in. wide, 3 ply, and 157 ft. long. The hides of about 1000 steers were used in their manufacture.

Gold Production of West African Mines in May

	Tons.	Value.	Profit.
Ashanti	11,018	\$177,000	\$58,000
Broomassie	3,214	73,400	36,900
Tarquah	4,910	67,200	12,400
Abosso	8,870	76,800	17,300

Sorting belts in the Coeur d'Alene region are protected from wear by cross-bars of flat steel riveted to them; at the Federal mines these turn up at the ends, giving the effect of a trough.

Combined Method of Analysis for Constituents of Zinc Ores

By FRANK A. BIRD

Decompose 5 gm. of the ore in a No. 1 beaker and cover with water. If the ore is a light sulphide or oxide, add 10 c.c. of nitric acid and potassium chlorate at short intervals to oxidize the sulphur, if necessary. If the ore is a heavy sulphide, use from 15 to 20 c.c. of nitric acid and sufficient potassium chlorate, or a saturated solution of potassium chlorate in nitric acid. The decomposition is effected as in any of the wet sulphur methods. A moderate heat will generally decompose the ore and prevent the formation of sulphur globules. Should sulphur separate out, transfer it to a No. 0 beaker and decompose it with a little nitric acid and chlorate, then add this to the main portion, which will save time. When all of the sulphur is in solution, evaporate the solution to a pasty condition and add 5 c.c. of water and 7 c.c. of hydrochloric acid, and reduce to dryness to expel the nitric acid and dehydrate the silica. Cool the residue and add 5 c.c. hydrochloric acid, heat to solution, and everything should then be decomposed. Add 20 c.c. cold water, 35 c.c. ammonia solution,¹ and a precipitant for manganese; 10 c.c. or more of hydrogen peroxide or bromine water. (Or ammonium persulphate salt, 0.1 to 0.5 gm. when the sulphur is not determined.) Boil 5 min. and filter into a No. 2 beaker, using a 9-cm. ashless paper. Label this 'Precipitate A.'

Lime.—Wash the beaker and paper alternately three times each, with hot water; reserve the beaker and place it under a funnel. Should the filtrate not smell strongly of ammonia, add a little more ammonia. Place solution on a hot-plate, and when boiling add sufficient ammonium oxalate solution² to precipitate the lime as oxalate. Continue the boiling about one minute and then set aside until the precipitate settles.³ Decant the solution through an 11-cm. filter-paper, retaining the precipitate in the beaker, to which add a little ammonia after most of the solution is decanted, mix by shaking, and then pour into the filter. Wash the beaker 4 times and retain it; then wash the paper 6 times, both washings being very thorough. With the paper still in the funnel, wash the precipitate back into the retained beaker. Dissolve the calcium oxalate by adding 5 to 7 c.c. of sulphuric acid which has just been added to two parts water; dilute to 200 c.c. with water of from 70 to 80°C. and titrate rapidly with potassium permanganate solution. Stop at the first permanent pink and add the filter-paper to the solution, after removing it from the funnel in such a manner as to collect any precipitate that has crept above it. Stir the paper in the solution a minute,

and then cautiously continue adding the permanganate to a final permanent pink; about 1 c.c. more will be required. The volumetric method for finishing is more satisfactory and accurate than igniting the precipitate, and where a series of estimations have to be made, it is more convenient and rapid.

Sulphur.—After receiving the calcium oxalate precipitate on the filter and washing the beaker in which the precipitation was made, remove the filtrate receiving the paper washings in some waste vessel. Acidify the filtrate with hydrochloric acid, add 3 to 4 c.c. excess, and boil. While the solution is boiling, precipitate the sulphur, as usual, with hot barium chloride solution,⁴ filter, and wash. Label this 'Filtrate A.'

Silica.—Heat 5 c.c. hydrochloric acid with 10 c.c. water and pour this over 'Precipitate A,' to dissolve the iron, etc.; change beakers, if necessary, running the solution through a second time or until everything dissolves. Notice that everything is dissolved in the decomposition beaker, and transfer all the insoluble material from it to a filter-paper. Wash the paper, ignite, and weigh as insoluble silica.

Zinc.—To the filtrate from the silica add 35 c.c. of ammonia solution and manganese precipitant, as before, omitting the water, and repeat the operation; filter through a new paper. With this double precipitation of the iron, all zinc will be in this solution and in 'Filtrate A,' which are to be combined after acidifying the last with hydrochloric acid. Washing with an ammonium chloride-ammonia solution is not necessary with two precipitations, and this method never fails.

To the combined filtrates add granulated lead, and about 15 c.c. more of hydrochloric acid, if the titration is to be made using ammonium molybdate as an indicator. Boil 10 min. and determine the zinc as usual with potassium ferrocyanide.

By decomposing the ore in a No. 1 beaker and throughout the operation avoiding excess of washwaters, the total bulk by the time the zinc titration is reached can be held between 250 and 300 c.c. In standardizing the ferrocyanide solution, work with an equal bulk of solution.

Iron.—Heat 5 c.c. of hydrochloric acid diluted with 5 c.c. of water and dissolve the iron precipitate, receiving it in the original decomposition beaker; boil the solution and reduce with stannous chloride. When cool, take up the excess with mercuric chloride, and transfer the solution to a No. 4 beaker, diluting to 400 c.c. with cold water; then add 10 c.c. of manganese sulphate solution⁵ and

⁴Five cubic centimetres of a hot 10% barium chloride solution precipitates 0.506 gm. BaSO₄, equivalent to 13.9% sulphur when working with 0.5-gm. sample.

⁵Zimmerman-Reinhardt's solution is composed of 160 gm. manganese sulphate dissolved in water to 1750 c.c., then 330 c.c. thick phosphoric acid (85%) is added, and 320 c.c. sulphuric acid. If preferred, reduction can be made in the usual way with granulated lead, zinc, or sodium sulphate; some operators only add 5 c.c. of the phosphoric acid when reduction is made with either of these three.

¹Prepared by mixing together 400 gm. ammonium chloride, 800 c.c. ammonia, and 1300 c.c. water. This amount fills a 5-pint acid bottle.

²For this solution, 40 c.c. of a 1:24 hot ammonium oxalate solution is sufficient for pure calcium carbonate = 56% lime.

³To be sure sufficient ammonium oxalate solution has been used, test a few drops of the clear solution with a drop of ammonia and some 10% solution of calcium chloride, a precipitate should form.

titrate immediately with potassium permanganate solution.

The following scheme appears to answer every requirement for the technical determination of lime in ores or limestones. It is rapid and does away entirely with ammonium sulphide for the precipitation of manganese and zinc, which when employed always entails a tedious and long-drawn-out process.

Treat 0.5 or 1 gm. of ore in a No. 1 beaker; if a sulphide, treat with 6 c.c. of hydrochloric acid, boil to about half the volume, then add 5 c.c. of

nitric acid and reduce to a pasty state. If the ore is oxidized, both acids can be added together.

When a pasty condition is reached, add 40 c.c. of water, 3 c.c. hydrochloric acid, 20 c.c. ammonia, and a precipitant for manganese, as in the above combined method. Boil 5 min. and filter through an 11-cm. paper, washing well with hot water. From here on, proceed exactly as in the combined method for lime: "Should filtrate not smell strongly of ammonia," etc. For all practical purposes, this method is equally as good as the longer ones.

Braden Copper Company

By POPE YEATMAN

*I have the honor to report that I have visited the Braden Copper Co.'s property in April, and the following covers, in general, the impressions of my visit:

The plant has not been entirely completed, but should be sufficiently so before the end of the summer to be able to handle at least 3000 tons of ore per day. The construction and operation of the plant has been delayed, due, first, to the abnormal weather conditions of a year ago; second, to some difficulty in obtaining labor; and third, to the installation of the Minerals Separation process for the concentration of the ores. The adoption of this process was decided upon last August, but all the machinery has not yet been delivered on the ground. Nevertheless, progress has been much greater than during previous years, and conditions are shaping in a very satisfactory manner.

Development Work

Considerable development work has been done, and especially in the Teniente section, where the main Teniente orebody has been explored for a distance of over 4000 ft., showing ore of excellent character; in fact, above the average grade. A connection was made in the shaft, extending from Teniente No. 1 to No. 2, and an ore-pass was completed, so that all ore taken out in development in the Teniente orebody can be sent to the mill. A few cross-cuts and raises have been driven, which still further prove the magnitude of the Teniente orebody. The principal work in the Fortuna has been on the No. 2 level, which is being extended so as to make connection by means of a winze with the Teniente tunnel, about 50 metres below. The faces of Fortuna No. 2 and Teniente No. 1 are now about 1000 ft. apart. The No. 2 Fortuna level has also shown considerable ore. A new level, Fortuna No. 2½, was started in order to mine ore between levels, it being found that the distance between levels No. 2 and 3 was too great to allow for carrying up the pillars safely. Improvements at the mine consisted of the erection of more dwelling houses, quarters for the Chileans, and enlargement of the plant.

Increased tonnage has been shown in the Fortuna orebody through the extensions of cross-cuts. The increase of fully-developed ore in the Teniente has

not been much, for the reason that the development work was done on only one level to prove the extent of the orebody in length and breadth, rather than the actual volume, which would necessitate the driving of several more levels above the No. 1. While not actually blocked, the Teniente No. 1 development has determined an orebody of great extent.

DEVELOPED ORE (1)		
Orebody.	Dry tons.	Copper, %.
Fortuna No. 2	2,123,627	2.85

" No. 3	41,200	2.13
	18,742,745	2.61

Robert Marsh, Jr., the mine superintendent, in his report of April 28, 1913, with which I fully agree, states: "Our greatest expectations lie in the Teniente mine. Here we expect to develop a large amount of ore above Teniente No. 1 level, and also between Teniente levels No. 1 and No. 3. The longitudinal section through this property shows graphically what we can fairly expect. We still have about 400 metres of virgin ground to connect with Fortuna No. 2. Of this, 200 metres shows attractive outcrops. It may be possible, however, that Teniente No. 1 level, being over 1400 ft. deep here, is a little too low for the best results.

"In addition, therefore, to the ore shown in the

*Report to the stockholders as consulting engineer.

above table, the following possibilities may be speculated upon:

	Tons.
Above Fortuna No. 2 and extensions.....	2,500,000
Above Teniente No. 1	10,000,000
Between Teniente No. 1 and 2 (Doubtful, if any)	
Extensions of Teniente No. 1 (above level).....	2,500,000

"From this it does not seem unreasonable to expect that ultimately 60,000,000 tons of 2.50% copper ore may be developed."

Though operating on a comparatively small tonnage, the costs have been very satisfactory, and it has been shown that the method of stoping will prove an excellent one. The electric railway, which gave some trouble, is working at a low cost and satisfactorily in spite of the heavy grade. Owing to the extreme toughness of the ore and the necessity for finer grinding, it was decided to increase the capacity of the crushing plant, and this is practically completed. During the past year a great deal of work has been carried on in the new mill, principally in connection with the installation of the Minerals Separation process, which has necessitated the introduction of Hardinge mills, Minerals Separation units, settling tanks for dewatering the pulp to a proper consistence for the Minerals Separation process, classifiers, launders, etc., but this work is not yet completed. Operations have been conducted partly with the Minerals Separation process and partly with the old wet concentration method, but, during the installation of the Minerals Separation process, it has been necessary to operate under conditions satisfactory to neither method.

Minerals Separation Process

The experiments were made with the Minerals Separation process, under the direction of the Minerals Separation, Ltd., last June and July, the plant being situated in the old mill. This test showed the advisability of the installation of the process, and it was arranged to change the method of concentration so as to make use of the Minerals Separation process and a greater profit per ton of ore treated. The first Minerals Separation unit was started in the new mill on November 14, treating material that would have otherwise gone to the vaners, but carrying the pulp less suitable for the Minerals Separation process than would be furnished when operating the plant with the proper installation of Hardinge mills. The results with the incomplete installation have not, of course, equaled what has been obtained in that part of the plant which is more thoroughly equipped. The work has shown, however, that an extraction in the concentrator of between 70 and 75% will be obtained. While these results may seem low, it must be remembered that some of the copper in the Braden ore is in the oxidized form, not capable of high extraction, either by the Minerals Separation or by wet concentration methods.

During the year, the second blast-furnace, 46 by 180 in., was erected and also a second Pierce-Smith basic converter. The second blast-furnace was started in April, and all the concentrate so far produced has been smelted. Owing to the stress of other work, the leaching plant had not been com-

pleted at the time of my visit, though roasting experiments had been carried out for some time. Since I left South America, however, the leaching plant had been started for a test run.

The production of sulphuric acid, owing to the small amount of conversion and absorption, has not been sufficient, and it has therefore been decided to add a lead-chamber to increase this. The narrow-gauge railway between Rancagua and the plant is in very much better condition than at the time of my last visit, owing to the fact that a greater amount of ballasting had been completed, trestles filled, and substantial culverts put in, replacing wooden trestles, and a number of curves of too small radius have been removed. Last summer (the South American winter) the abnormal rains caused many delays from wash-outs, as was the case with practically all the railways in Chile.

Power Station

The electric power station is completed with the exception of a fourth unit, which will serve as a spare or for the operation of the present leaching plant. So far it has not been necessary to run more than two units, and neither of these at full capacity, but with the increased production of the next few months, the three units will have to be run regularly. The abnormal weather of last year also caused wash-outs on the canal and caused some delays last winter. Much of this should be obviated in the future. During the last year improvements have been made in the way of erection and completion of staff quarters, store and warehouse, and single and married quarters, both for the Chileans and the foreigners. Probably the largest piece of outside work has been in the direction of the flume line and dam, to cut out the tailing, which heretofore had gone into the Coya river.

The next few months will witness a decided increase in production. Enough has been done to prove that the cost for producing copper will be below the limit estimated some years ago, namely 7.5c. The developments in the mine within the last year, coupled with work done in treating ores, gives added confidence in the future of the property and suggests the desirability of increasing the scale of operations.

Dredging the Cucaracha Slide, Panama

A relay pumping station is being installed on the west side of the Culebra cut, near the bridge of the Panama railroad over the Rio Grande, in anticipation of dredge excavation at the foot of Cucaracha slide. The plan as at present contemplated involves passing the discharge pipe-line of two suction dredges across the cut on pontoons, and up the west bank to the relay station; thence down the valley of the Rio Grande about 4000 ft., to discharge west of Cerro Luisa, the hill at the outer end of Pedro Miguel dam. It is probable that an earth dam will be thrown from the lower end of Pedro Miguel lock to the hills on the other side of the river, a distance of about 1500 ft., and the swamp west of the lock will be filled with spoil from the slide.—*Canal Record*.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Minerals Separation v. De Bavay Process

The Editor:

Sir—I have read with great interest T. J. Hoover's book on flotation and also the article by Edward Walker in your January 4 issue. Having been closely connected for a number of years with both the Minerals Separation and De Bavay processes in Australia, where they are being used on a large scale, I would offer a few suggestions as to a comparison of these processes.

In comparing the De Bavay process with the Minerals Separation process as used on Broken Hill ores, many factors have to be taken into account. In the first place, the De Bavay company was the first to recognize that in the treatment of Broken Hill tailing it does not pay to treat the slime product, owing to the high percentage of lead that it contains. By rejecting this slime it has been found that not only a higher grade, and consequently a more profitable zinc concentrate is produced, but the slime itself is kept on hand as a valuable by-product.

Mr. Walker remarks that experience gained during the past year has gone to prove the efficiency of the Minerals Separation process over the De Bavay process. This certainly does not appear to be the case, judging by the enormous profits made by the De Bavay company, in spite of the fact that it paid higher prices for the tailing. Also, an interesting point in this connection is the fact that the South Mines, after various trial runs, decided that, from a commercial point of view at any rate, the De Bavay was the best process. This certainly does not point to the process being inefficient as compared with the other processes which are being worked on Broken Hill ores. From a profit-making point of view, the De Bavay process is ahead of any other process that is working on Broken Hill tailing at the present time. I do not refer to the slime. At the present time there is not much profit in the treatment of slime, but it is hoped that the experiments that are being conducted by the South Mines, Amalgamated Zinc, and other companies will be crowned with success. Mr. Walker further states that, moreover, there is little likelihood of the De Bavay process being applied anywhere else than at Broken Hill, as it is obviously of inferior efficiency to the Minerals Separation process. Why obviously? In the first place, Broken Hill is not the only lead-zinc mining centre in the world, and also, with their present knowledge, the De Bavay people could greatly simplify the design of their plant, making it cheaper to erect. Mr. Walker would be greatly surprised if he knew the actual working cost of this process. I regret that professional etiquette prevents me from giving this information. The recoveries are also high, higher than those given in Mr. Hoover's book, in which a crude value for the tailing is conveniently assumed, would lead one to

believe. Both the De Bavay and the Minerals Separation process have their scope, but on different types of ore. The De Bavay process will treat material through 30 mesh with 5 to 10% slime, which is much coarser than can be treated by the Minerals Separation process without crushing. For exceptionally fine-grained ores, for which the Minerals Separation process is eminently suited, the De Bavay process is not so good. In experimenting with the De Bavay process, the method described by Mr. Hoover, in his book on flotation processes, is not suitable, as it will give bad results on any ore. Although I have personally conducted numerous experiments on the De Bavay process, I have never used or seen used anywhere the method referred to above. The stepped cone, or rough design shown in Mr. Walker's article, I have never seen on the De Bavay plant, as the engineering skill of the De Bavay company is more up to date and more original than the design would lead one to believe. The De Bavay process stands as a model of Australian management and metallurgical skill, so lightly spoken of by Mr. Hoover.

In reference to the Minerals Separation process, it is not generally known that it is a development of the Cattermole process. The first plant erected at the Central mine was really a large Cattermole plant using Wilfley tables. In observing the tailing from these tables falling into the tailing boxes, a froth was seen floating on the top of the boxes. Immediately the Central mine staff planned out the scheme of flotation boxes and the treatment was modified accordingly. It will be seen that the process was made commercially successful by the Central mine staff and that Australians had no small share in its development. Thousands of pounds profit were made by the Minerals Separation process on zinc tailing before Mr. Hoover's single-level apparatus, which is undoubtedly the finest mechanical feature of the present plant, was introduced. To Mr. Lavers, chief metallurgist of the Minerals Separation, Ltd., in Australia, is also due the rapid advance of this process in treating copper ores, owing to his brilliant research into the adaptability of eucalyptus and other oils to the treatment of these ores without the necessity of the use of acid.

WILTON SHELLSHEAR.

Mt. Morgan, Queensland, May 8.

A Correction

The Editor:

Sir—In your issue of June 7, 1913, under 'General Mining News' for the state of Nevada, on page 875, you state that the plant of the Nevada New Mines Co. "consists of a crusher, ten stamps, tube-mill, agitators, and Oliver filter." This Company has a Hardinge conical pebble mill in operation, which we believe your correspondent has mistakenly called a tube-mill. Will you kindly correct this misstatement in your next issue, and oblige

HARDINGE CONICAL MILL COMPANY.

New York, June 13.

Coinage executed at the United States mints during the year ended June 30, 1913, was valued at \$37,147,000, of which \$30,058,000 was in gold.

ably more than that amount, with good reserves left. Drifts are now being driven both ways on the vein, raises are being cut at several points, and preparations are being made to sink on one orebody. There appear to be two pay zones discovered, each lying approximately with the dip of the vein, this being about 35° from the vertical. The mine is equipped at present with a 10 by 10-in. belt-driven compressor, from a 60-hp. motor, Waugh stoping drills, and several piston drills, side-dump ore cars of one-ton capacity operated by mules in trains of five or six cars, and a mill of ten stamps, with rock breaker, vanners, and other machinery. The intention is to put in ten more stamps and to increase the air-supply by installation of larger compressor as soon as the new road is opened. Abe Hall, of Grass Valley, is superintendent.

The Twenty One, below Tightner, on Kanaka creek, is being developed by San Francisco people, and is the deepest mine in the 'camp.' It is said to have a strong vein and some good ore developed. The Sixteen to One, above the Twenty One, had a body of high-grade ore several years ago, and is still being developed. Rainbow, on opposite side of Kanaka creek, is working a downward continuation of an orebody discovered and worked in an old gravel channel above. It has a long adit from Kanaka creek cutting the lead at 1500 ft. below the Chips Flat placer diggings. It is said to have considerable pay ore developed, but suffered the loss of its entire plant in early May, as result of placing living quarters too close to the mill. The intention is to rebuild, this time with 20 stamps and more modern concentrating machinery. The compressor has been re-erected and development is proceeding. L. P. Woodbury is president and manager. The Plumbago is near the south end of the district. It is a famous mine with a tremendous amount of development work on a strong east-west vein, and is very regular, dipping 30° from vertical to the north. There is a great extent of low-grade quartz left, largely as pillars, with the greatest development on line of the so-called Robinson shoot, where the vein is 8 or 10 ft. wide. A 20-stamp mill is in rather poor shape, but operating steadily. The place is taking on renewed life under active policy of the new superintendent, A. J. Pierson, lately from Phoenix, Arizona. This property has its own power plant on the Middle Yuba, about a mile and a half from the mine, whence compressed air is carried through a 5-in. line, while a separate generator furnishes current for mill power and for lighting. With investment of more capital to put it in good shape and for deeper development, it may easily become a large producer again. The Gold Cañon is on the Yuba, just below the Plumbago power-house. C. C. Derby is in charge as mining engineer, and is developing the downward course of an ore-zone evidently associated with the intersection of the vein and the contact which it crosses, as noted before. The property has a 5-stamp mill and is well equipped with compressor plant, etc., all operated by water-power developed with a high head. Sufficient ore of good grade has been found in development to keep the mill going with good results.

The Oriental, toward the west edge of the district, is on an east-west vein and was extensively worked from a shaft on the outcrop in early days. Afterward it was purchased by people controlling the Plumbago, and was developed by a cross-cut 4000 ft. long, tapping the vein at 1400 ft. below the outcrop and 600 ft. below the bottom of the old shaft, to which a raise was made. Little more seems to have been done, but considering its advantageous position, it would apparently warrant the considerable investment necessary to further develop the lower portion of the vein and equip with a milling plant. The vein is said to be strong and productive in the upper portion. The Kate Hardie, still farther west, has been worked intermittently for a long time, and is still being worked with fair results. The vein is narrow, but produces some high-grade ore. The Kenyon, on the creek below the Oriental, but on the opposite side, has a good record for production, but is now closed. Conditions in general in Alleghany county point to increased mining activity and the conduct of milling operations on a large scale.

JOHANNESBURG, TRANSVAAL

THE ROBINSON MINE.—CONCENTRATION OF MINING AT CROWN MINES.

Among the richer mines on the Rand, unfortunately fast approaching exhaustion, the old Robinson is of especial notice. Last year's results were not by any means low; for, taking the year on the whole, the mine continued to earn the highest profit per ton of any mine on the Rand. The total revenue last year was £1,260,529, or an average of £2 3s. 8d. per ton milled. Working costs were £451,769, or 15s. 8d. per ton, leaving a working profit of £808,760, or no less than 28s. per ton. Satisfactory as are these figures, they do not compare well with the early achievements of this mine. Starting milling operations in 1888, when ore-reduction methods on the Rand were crude compared with those of today, the recovery averaged no less than £12, the costs of working being at that date about £3, thus leaving a working profit of £9 per ton. In two years the yield fell, however, to £5 per ton, and the working costs to £2, while five years ago the yield was under £3 per ton. Since milling operations commenced at the Robinson mine, over 6,000,000 tons has been crushed, and 4,115,137 oz. of gold recovered, of a total value of £17,300,000, or an average of 58s. per ton. Of this large amount, over £9,000,000 has been paid in dividends. The mine is, however, rapidly approaching exhaustion, and has already ceased to hold the reputation of having the highest yield of any mine on the Rand, that distinction at the present time being held by the Meyer & Charlton. Last year the development footage at the Robinson showed a marked decline, and only amounted to a total of 5823 ft., and soon the whole of the mine area will have been developed.

The Crown Mines Co. may be regarded as the pioneer of what, for want of a better definition in Rand mining, is called the Kimberley system of mining, the chief features of which are to concentrate all underground operations as closely as possible. To carry out this idea, a large main level is being driven, on the horizon of No. 13 level, from one end of the property to the other, and which is now completely equipped and at work between No. 1 and 7 shafts. During the year, this level was driven 984 ft., and is already 1567 ft. west of No. 7 shaft, but it has still 4500 ft. to be driven before it reaches the western boundary of the property. This level is equipped with an elaborate electric-haulage system, and is intended to deal with an output of 10,000 tons per day, and to supply both No. 5 and 7 shafts with ore. New crusher stations have been erected at the head of these two shafts, and a system of electrical transport of the crushed ore to the mills arranged in such a manner that all the mills are linked up with the system. Over £1,250,000 has been spent in this work, and when the whole arrangement is in full swing, lower costs and higher profits are looked for. All the large amalgamated properties on the Rand are now adopting this system of main-receiving levels for the concentration of underground operations, and in the face of the higher costs of working in general on the Rand, it is hoped that the system will bring about the expected reduction in working costs.

BUTTE, MONTANA

COLLAPSE OF BUTTE CENTRAL.—BUTTE & SUPERIOR AND ELM ORELU.—SECONDARY ENRICHMENT AT BUTTE.—A. I. M. E. MEETING.—NEW COPPER DISTRICT?

For the second time the old Ophir mine has proved disappointing to its owners. After a meteoric career in the stock market and in the newspapers, the Butte Central Copper Co. is rapidly dropping into oblivion, leaving its stockholders in a bad mood. The mine and mill are now closed and attached by unpaid employees. The former collapse came after a vain attempt to make a copper mine out of a typical manganese-silver vein. The present calamity results from imagining the existence of commercial silver-gold orebodies where none were to be found. Both failures were due to lack of conservative engineering advice as against that of the old-time miner and practical man. It is one of the numerous cases where it is difficult

to fix the blame. The whole miserable fiasco can be adequately explained on the grounds of ignorance and inexperience in the executive side of mining. If the directors had been wise enough to take their money and mine to reputable engineers in this country or in Europe, and say, 'Here is what we have, can anything be done with it?' they would have been told, after proper investigation, either to distribute their money or look for something else to invest in. But in such a promotion as Butte Central, the promotion and management of the enterprise usually get so badly interwoven that the men who raise the money usually want to run the mine in person, partly from a sense of responsibility to their clients, it may be, but also, in many cases, because of the remuneration connected with such management. Such remuneration may be either direct in salaries, as in the promotions of Stephen R. Dow of Boston, or indirect, as inside information useful in stock manipulation.

It is rumored that the Butte & Superior Copper Co. and Elm Orlu Mining Co. have been considering consolidation in order to avoid the troubles of probable litigation over doubtful orebodies. W. A. Clark, of the Elm Orlu interests, denies this, however. It is at least certain that both parties are doing everything possible to avoid bringing their differences into the courts, and the community at large wishes them success. In the meanwhile, the Butte & Superior mill is doing good work with the zinc ores, and the Elm Orlu is not pushing the construction of its much-heralded mill on Timbered Butte. All of which is food for thought.

Butte can claim distinctions of many kinds—namely, largest mines, biggest copper productions, biggest mining town, strongest labor unions, ugliest appearance from a distance and possibly from nearby, worst moral reputation undeserved, etc.—but one of its unique distinctions is as a battle-ground for theorists on genesis of ore deposits. It certainly has them guessing, and they come in numbers to examine the 'strange' orebodies and speculate on their origin. The bone of contention is the copper-glance ore. According to all theories held heretofore, this should have been worked out long ago. But the mines are still in operation. Neither has the chalcocite cut out, which causes much comment. A big battle of geologists will probably take place in August, when the American Institute of Mining Engineers meets at Butte. Some people think that the chalcocite did not form from descending sulphate solutions, with attendant secondary enrichment, and will be there to prove it. Others are equally convinced that that is the way it did form, and will also be there to prove it. The advance guard of some of the contestants has already arrived in the persons of L. C. Graton and their associates, who are here with apparatus for investigation. The Graton-Murdock idea of examining the ore relations microscopically is really something new, and worth while. Incidentally, these geologists will have one big advantage, in that their opponents will have to get microscopes and polished sections, too, before they can dispute anything. Mr. Graton and his crew are out to clean up this subject of secondary enrichment of copper in general. They expect to spend several years at it, from Alaska to Mexico, and possibly elsewhere. They are a 'live bunch' of young scientists, and something should come from their endeavors.

The geologists are not the only ones interested in the August meeting of the American Institute of Mining Engineers at Butte. In fact, in point of numbers, the geological papers are almost eclipsed by the metallurgical and mining papers. More than 40 papers have been prepared for this meeting, and nearly every phase of milling and smelting practice in Montana will be covered. These papers, and the resulting discussion, promise to be so instructive that no live metallurgist can well afford to be absent, and it is probable that very few of them will be. The thoughtful ones are already making hotel engagements for themselves and friends, and the local committees are busy making things ready for the mental and physical needs of their fellow engineers.

There is so much loud talk going the rounds about a

'second Butte' in Flathead county, Montana, that we are beginning to think that some of the old Nevada expert boosters and 'wind-jammers' have invaded the land. Nothing is known here against the new camp except the talk and newspaper mining. It is hoped that it will prove ten times bigger and better than Butte, if only for the purpose of giving the Copper Producers' Association something new to think about. It must be confessed that, so far, no intelligent coördinated description of the conditions has been forthcoming. These mysterious new bonanzas

END-VIEW OF 2400-VOLT GENERAL ELECTRIC LOCOMOTIVE.

are said to be northeast of Flathead lake, about 30 miles south of the Great Northern railway, and of course in a densely wooded, out-of-the-way locality.

The electrification of the Butte, Anaconda & Pacific railway is nearly completed, and the electric locomotives will soon be displacing the steam-engines. The electrical engines are queer but powerful-looking affairs. They resemble from without old stubby box-cars, such as section gangs inhabit on the sidetrack. They are not impressive and powerful-looking like the big steam locomotives they are to displace. But looks are deceptive, apparently, as they can pull more than their predecessors, and cost more, too, \$40,000 being the price of each in round figures. As the main ore line for Anaconda passes through the best residence section of Butte, the people are glad to see the change coming, in the hope that the new motive power will not be so noisy and dirty as the old steam-engines.

The slime and sand from the concentrator at Anaconda are being made into tile and bricks at the Washoe brick plant. The product is experimental so far, but gives promise of success.

NEW YORK

BRADEN REPORT.—CHILE COPPER.—METAL PRICES.—AMALGAMATED DIVIDEND.—OHIO COPPER.—MEXICAN CONDITIONS.

The expected increase in the ore reserves of the Braden mine was announced in a report by Pope Yeatman, made at the stockholders' meeting June 23. The report is reviewed on page 19. Earlier in the week Braden called for redemption \$68,500 of its 6% bonds, and a few days later canceled the call on the ground that redemption might lead to dissatisfaction on the part of those bondholders who paid higher prices for the bonds than the redemption figure. Braden bonds sold as high as 210 when the stock was at 10½, so that the present level of around 7 is a poor one at which to effect conversion. There have been persistent rumors that some new financing of Braden will be necessary, but they have been as persistently denied. Thomas W. Proctor has been appointed a master by the Supreme Court in Boston to hear the suit of Louis Ross against A. C. Burrage to recover a share in the promotion

profits of the Chile Copper Co. As it is expected to have that Company at work within three years, producing copper at the rate of 300,000 lb. per day, at a cost of 6c. per pound, it looks as though the supply of cheap copper is in no immediate danger of exhaustion. At any rate, that is evidently the view of the consumers, for none of the big buyers have come into the market during the past week. Producers hope for a speedy resumption of buying at the 15c. level, but meanwhile small lots have changed hands at as low as 14½c. European sellers are reported to be out of the market for July-August deliveries, indicating that they are sold out of spot. As much spot remains to be purchased, the sellers have the London spot situation in their hands. The A. S. & R. Co., on June 27, was quoting £69 in London. The Nichols refinery is still tied up by the strike, so Phelps, Dodge & Co. are entirely out of the market. Small sales of lake copper were made at 13½c. by a company which needed the money more than the copper. Consumers freely state that they are in no hurry to buy, expecting to get bargain prices later. Exports of copper for the week ended June 26 were 5228 tons, a total since June 1 of 25,341 tons. Exports during the same period last year were 21,930 tons.

Reduction of the dividend rate of Amalgamated Copper is rumored, and is evidently more than a possibility, since the copper metal market is so weak and is threatening to sag lower. Amalgamated is a peculiar stock; it sells now but little above A. S. & R., although it is paying 6% and the latter only 4%. It is quite possible that the decrease has already been discounted, just as the stock sold at a higher figure just before the increase to 6% was announced last fall than it has at any time since. Giroux stockholders have already deposited more than a majority of the shares of that concern for exchange in the new Coppermines merger. By the laws of Delaware, 65% of the stock

and until this work is finished no reorganization plans will be formulated. It has always been claimed that this coal property formed an exceedingly valuable asset, and the investigation of the value will be a correspondingly careful one.

Mexican railways are in a nervous state. It was reported on June 27 that the National Railways of Mexico had been placed in the hands of a receiver, J. M. Galbraith, the manager in Mexico City for the Waters-Pierce Oil Co. Following the announcement of the resignation of E. M. Brown from the presidency, this created some consternation, but the report is doubted by the banking houses concerned. The resignation of Mr. Brown is also denied. Nevertheless, it is evident that the situation of the railway is bad, and it would not be strange if before long the Mexican government has the obligations and the bankers have the railway. A report from the United States Consul at Chihuahua states that railway communication has been shut off for more than three weeks, and the latest reports from Chihuahua indicate that everything south of Juarez is in the hands of the Carranzistas, and Juarez may fall at any time. General Pedro Ojeda tried to force his way from Guaymas to Hermosillo, but was beaten back, and Guaymas is nearly in the hands of the state forces. On July 1 the bankers interested will offer for sale \$8,500,000 of the 6% Mexican government bonds, and \$14,250,000 will be issued in France, and \$7,250,000 in England. It is reported that the French bankers are taking them at 89 and hope to sell them for 95 or better, so Mexico will have to pay well for her money. The A. S. & R. Co. has been having a hard time in Mexico during the past year, as the operations have only been on a 50% basis at times and are now about three-quarters of normal, with one more furnace about to be blown in at Aguascalientes and two more at Monterey. Earnings are

FEDERAL SOLDIERS IN CAMP.

must be exchanged in order to give the Coppermines company "physical control" of the Giroux, and the deposit of shares is expected to reach that figure before long. It is stated that leading interests in the merger have agreed to underwrite a large part of the \$3,000,000 7% bond issue which it is proposed to float.

After having been postponed four times, the annual meeting of the Ohio Copper Co. was held in Boston on June 25. The board, as elected, consists of W. O. Allison, F. A. Heinze, J. W. McKinnon, J. W. Pierson, Jr., W. C. Lewis, W. I. Badger, and Maurice Levy. Mr. McKinnon represents the Assets Realization Co., controlling 163,000 shares of Ohio which formed part collateral of the \$1,000,000 loan negotiated by the United Copper. Mr. Lewis represents Walker Bros. of Salt Lake City, and Mr. Badger is said to have been elected because of large personal stockholdings, although he has acted as legal representative for Heinze for a number of years. It is said that Heinze no longer controls Ohio, and will probably not be elected chairman of the board at its organization meeting. The United Copper is about to drill its coal property, held by the New York & Pennsylvania Coal Co.,

showing a decrease, but the company officials maintain a cheerful attitude. Rumblings of a threatened suit by the Government for the dissolution of the 'Smelter Trust' continue to be heard, so the stock market outlook for the 'Guggenheim' issues is not as bright as it might be.

JOPLIN, MISSOURI

UNDERWRITERS LAND CO. ACQUIRES YELLOW JACKET LEASES.
—MINING FROM FLAT-BOATS IN DRIFTS OF YELLOW DOG MINE.—ZINC AND LEAD NOTES.

The Underwriters Land Co., operators of the Priscilla mine in the West Joplin district, has acquired the fee to 132 acres of the McBee land in the Klondike camp, six miles northwest of Joplin, for a consideration of \$50,000. J. H. McBee and associates owned the tract, which was not worth \$50 an acre, so far as was then known, three years ago. Development by the Yellow Jacket Mining Co. disclosed good zinc and lead deposits, the former ore predominating. O. W. Sparks opened the Yellow Jacket mine, which is a good producer of top-grade zinc sulphide ores. The fath of the Underwriters Land Co., which has operated

in the Missouri-Kansas-Oklahoma district for many years, in the future possibilities of the zinc and lead industry, is one of the best advertisements the district can have.

While the Underwriters company is extending its work in the West Joplin districts, work has been suspended in the formerly rich mines north of Webb City. The pumps have been withdrawn from the old Yellow Dog workings and the water has risen in the old drifts. Sub-lessees are working the rich old pillars that yet remain. They carry the ore from these pillars to the shaft with the aid of large flat boats. It is hoisted to the surface and cleaned by hand jigs. The Yellow Dog is one of the famous old producers of the district. The removal of the pumps will make pumping operations much more difficult in adjoining properties to the south. A substantial concrete dam separates the Yellow Dog drifts from the workings of the mines to the south. When the water rises over this barrier, which is 27 ft. in height and about 75 ft. long, the workmen in adjoining mines will be working far beneath the water-level of this expansive underground lake, which will be scores of acres in extent. The pumps at the Yellow Dog were throwing 3000 gal. per minute, or 4,320,000 gal. per day. The concrete dam is constructed at a depth of 200 ft. beneath the surface.

Interest in large mining operation centres in the West Joplin district, at this time, where some big milling properties are being opened. On the Riseling estate, sheet ore is being blocked out in a number of drill-holes at a depth of approximately 200 ft. The surface is flat prairie and has not been mined extensively. It has only been within the past few years that mining operations of any importance have been carried on in this region. The ore as a rule shows a mill recovery of about 3.5% zinc sulphide with some lead. In places, the lead ore is especially rich. The sheet-ore district is being blocked out over an area of three miles east and west, and about two miles north and south. Among the operators that are active in this work are O. W. Sparks, J. M. Short, the Underwriters Land Co. and the St. Louis-Joplin Lead & Zinc Co. Work on the latter's land is of unusual interest, in view of the greater extent of the mineral formation.

A new concentrating plant is being constructed by the Kansas City Mining Co. on a lease of the Rex land, east of Joplin. The shell of the mill was moved from the Duenweg camp. Dirt from half a dozen small 'gouges' will be handled over the plant. Drilling for deeper ore is now in progress.

LONDON

ZINC CORPORATION AND FLOTATION PROCESSES.—MUREX MAGNETIC CO.'S AFFAIRS.

On many occasions I have given records of the doings of the Zinc Corporation, which was formed in 1905 by Bewick, Moreing & Co. for the purpose of treating the great stacks of zinc tailing at Broken Hill. The early days were occupied in accumulating expensive experience in connection with the many flotation methods then attracting attention. Engineers with varied experience attempted to apply the rival processes, the action of which was little known. Eventually the Elmore vacuum plant came to the rescue of the almost bankrupt company; but in 1910 the improved Minerals Separation process asserted itself as by far the cheapest in first cost and in working, besides having a wider scope as to material. During the past two months two subsidiary processes have been adopted, of which details are given later. In the middle of 1911, it was decided to acquire the South Blocks mine, and thus become a mining company, instead of depending on dumps and tailing produced by other companies. A further venture in this direction is to be chronicled in the acquisition of the control of the Sunny Corner mine in New South Wales, floated as a separate company called 'Zinc No. 1.' The South Blocks mine contains two lodes outcropping on the surface, in which lead and zinc predominate, respectively. Development has been centred on the lead lode. On the first seven levels, this lode has proved to average about 10 ft. wide, but on the eighth it is no less than 80 ft. wide. An inspection of the

mine plans leads to the conclusion that the zinc lode also is a spur of this deep wide lode. As the ore disclosed on No. 8 level is higher in quality than the average of the mine, it is obvious that the outlook is excellent. As regards the two new processes mentioned above, the first is the invention of the mill foreman, James Lyster. Its object is to float the galena out of the slime produced in the lead-concentration plant that treats the ore from the South Blocks. The second is E. J. Horwood's roasting process intended for the treatment of the zinc slime that comes from the zinc-concentration plant. Mr. Horwood's process consists in giving a roast at a low temperature sufficient to coat the galena with sulphate, but not affecting the blende. Thus, in subsequent flotation, the blende rises and the sulphated galena sinks to the bottom. I should add that the flotation business, since the erection of the Minerals Separation plant in 1910, has been in the hands of Theodore J. Hoover, first as engineer to Minerals Separation and subsequently as managing director of the Zinc Corporation. During the year 1912, 138,284 tons of South Blocks ore was treated, averaging 15.3% lead, 9.16% zinc, and 2.57 oz. silver, from which 25,227 tons of concentrate was recovered, averaging 67.3% lead, 6.2% zinc, and 9 oz. silver. The zinc-concentration plant treated the zinc tailing from the lead plant, and tailing from the various purchased dumps, the total being 345,425 tons, averaging 14.41% zinc, 5.5% lead, and 6.94 oz. silver. From

ZINC CORPORATION PLANT AT BROKEN HILL.

this, 85,354 tons of zinc concentrate was obtained, averaging 47.2% zinc, 7.4% lead, and 12.5 oz. silver, and 10,881 tons of lead concentrate averaging 57.9% lead, 14.8% zinc, and 32.2 oz. silver. The sale of concentrates brought an income of £644,428, and £206,433 was distributed in dividends.

Mr. Hoover has recently extended his interest in flotation by becoming consulting engineer to the Murex Magnetic Co. This Company provided one of the Stock Exchange booms four years ago, and the shares were rushed to absurd prices. The people behind it were connected with the Shell oil group. As has often been recorded, the process consists of adding oil and magnetite or other magnetic mineral to the crushed ore, and removing the agglomerated magnetite and sulphide by means of magnets. The advantage is that, as no acid is used, the process can be applied to ore that contains much calcite or other carbonate. The process is in use at Corboda copper mine in the South of Spain, at the Whim Well copper mine in the northwest of Western Australia, and at mines in France and Germany. But the board and control have proved to be inefficient in business instincts. A bad mistake was made in connection with the terms under which the South Blocks Extended mine was financed by Murex funds, and the whole of the money thus advanced has been lost. The Company is at the end of its financial tether, and is to be reconstructed with the object of raising a few thousand pounds in order to continue its existence until such time shall arrive that substantial royalties are received. The shareholders have done well in putting things in the hands of an expert with good connections like Mr. Hoover. Under the old regime, engineers all over the world were inclined to regard the Murex company dubiously. They will be more ready to investigate now that a reliable engineer is at the helm.

General Mining News

ALASKA

JUNEAU

The Alaska Mexican stamp-mill crushed 20,286 tons of ore in May, producing \$54,052 from amalgamation and concentrate. Operating expenses were \$23,591, and construction \$2180, leaving a profit of \$28,280.

The Alaska Treadwell stamp-mills crushed 71,512 tons of ore, producing \$190,072. Operating expenses were \$85,486 and construction \$8197, leaving a profit of \$96,389.

The Ready Bullion and 700-Ft. Claim mills of the Alaska United crushed a total of 36,672 tons of ore in May, yielding \$84,452 from amalgamation and concentrate treatment. Operating expenses were \$56,430, and construction \$2181, leaving a profit of \$24,841.

ARIZONA

COCHISE COUNTY

The Mascot Copper Co., three miles from Dos Cabezas and about 17 miles east of Wilcox, the nearest railroad point, promises to begin shipping shortly.

Ore-bins are being built at Wilcox, and auto-trucks will be used to haul ore and supplies to and from the mine. A steam hoist of 1000-ft. capacity has been installed. Two drills are in operation, and one hole was put down 1500 ft. In Dos Cabezas mountains, good vanadium ore has been discovered.

GILA COUNTY

(Special Correspondence.)—At the New Keystone mine, retimbering of all the drifts has been completed. As there has been no work in the way of development performed during the past year, the ore reserves are still estimated at 2,500,000 tons of 2.25% copper ore. The delay in treatment of Keystone ore is accounted for by the existence of so much oxidized ore in the property, rendering treatment by the usual methods uncertain. R. C. Canby, who is experienced in low-grade ore treatment, will subject the Keystone ore to thorough tests during the coming months. It is probable that his experiments will include the erection of a small experimental mill on one of the extra foundations laid down when the Miami mill was built, especially so, as the experiments to be conducted by Mr. Canby will be valuable to the Miami company, with its large tonnage of oxidized ores which must be treated by leaching. Mr. Canby laid out a program of tests here in March, and since then has been investigating the recent developments at Anaconda and other large plants throughout the country. He was in charge of the old ferric-chloride process tested by Hunt and Douglas twenty years ago.

The position of the Iron Cap is improving every day. The cross-vein found recently has been cut in both directions until the width of the orebody at this point is 30 ft. The face of the main drift continues in rich copper ore, and has straightened out again to its main easterly course. On the 800-ft. level the same vein is being followed from a point about 78 ft. east of the shaft.

Miami, June 25.

(Special Correspondence.)—The Apache group of claims, situated in Richmond basin, and owned by Pfeister Bros. of Globe, has resumed shipping ore to the Old Dominion smelter. The ore averages 25% copper and is high in iron content. It occurs in a contact of lime and quartzite. Transport over 12 miles is done by mule-teams.

Miami, July 1.

Improvements at the Ray mill at Hayden, consist of three more settling tanks to take care of overflow water from the 16 concentrate bins; the return water pipe-line is finished; and two more Green chain-grate stokers are being installed at the power-plant.

The Old Dominion Copper Mining & Smelting Co., at Globe, will place in operation additional electrical equipment, including two 815-kva. alternating-current generators; two 100-kva. synchronous motors; one 150-hp., six 75-hp., one 50-hp., one 20-hp., and three 10-hp. motors, and

switchboard panels. This apparatus has been ordered from the General Electric Company.

MOHAVE COUNTY

The Gold Road mine produced \$80,000 in gold during three weeks of June.

A cross-cut on the 250-ft. level of the Silver Hill mines at Chloride, disclosed a body of ore ranging from five to seven feet, the average value of which is said to be in excess of \$70. This mine has been idle the past 25 years and the ore was only found on the property by accident.

A large orebody has been opened in the New Jersey mine, at Chloride. The drilling plant for the Kingman Copper Mining & Milling Co. will soon be ready for installation. The Tennessee mine shaft, at Chloride, is being sunk deeper. Good ore is being opened on the 900-ft. level.

PIMA COUNTY

(Special Correspondence.)—The Empire Zinc Co. is working about 40 men on the old San Xavier claims in the Pima district, some 20 miles south of Tucson, and is shipping about 50 tons of ore per day. The ore contains silver and gold. The copper-bearing portions of the claims will soon be worked again.

Tucson, June 26.

The Old Mammoth mine, which has produced a great deal of gold, has been bought by the Great Western Copper Co., represented by W. J. Young and brother, for a consideration said to be about \$150,000. The deal was closed in Detroit with the previous owner, named Fletcher. The Great Western Copper Co. has had engineers testing the ore for the past two months. Development will be started on the 700 and 800-ft. levels. Below the former level there is said to be a large shoot of ore carrying gold, \$9 per ton, and 4 to 6% copper.

YAVAPAI COUNTY

(Special Correspondence.)—The Hull tunnel has been driven more than one mile, and is to be cut right through the mountain. A winze is being sunk 5000 ft. from the entrance to the tunnel, on a promising vein opened by the tunnel at that point. The tunnel will connect underground with claims on both sides of the mountain.

Jerome, June 26.

Ample capital has been provided for the development of the Harqua Hala mine of the Yuma-Warrior Mining Co. This mine has produced a good deal of gold in the past.

The Hidden Treasure Mining & Development Co. is sinking the winze from the adit of the Monte Cristo mine. The bottom of the winze shows 10 to 14 in. of rich gold and silver ore.

CALIFORNIA

KERN COUNTY

The Midway Gas Co. will increase its delivery this week from 7,000,000 to 15,000,000 cu. ft. per day, following the bringing in of new gas wells in its territory. The Associated Oil Co. has recently brought in two new gas wells, and the Honolulu Oil Co. another. The new production within the past few weeks will amount to nearly 100,000,000 cu. ft., open measurement, which will be reduced to 15,000,000 to 20,000,000 ft. under pressure sufficient to carry to Los Angeles.

SIERRA COUNTY

A stamp-mill may be erected at the Red Ledge mine, 7 miles west of Alleghany. J. B. Moulton is in charge. The 3-stamp mill at the Kate Hardy, at Forest, is working again. Mine development is encouraging. A. D. Grant is in charge.

TRINITY COUNTY

(Special Correspondence.)—The Enterprise is the only mine being worked in the Helena district. It is operated under lease by R. H. Skinner, J. D. Day, and F. C. Meckel. The 16-stamp mill is working one shift, but as there is plenty of ore opened, another shift will be started. Other properties are being prospected, and generally the position is encouraging.

Helena, June 20.

TUOLUMNE COUNTY

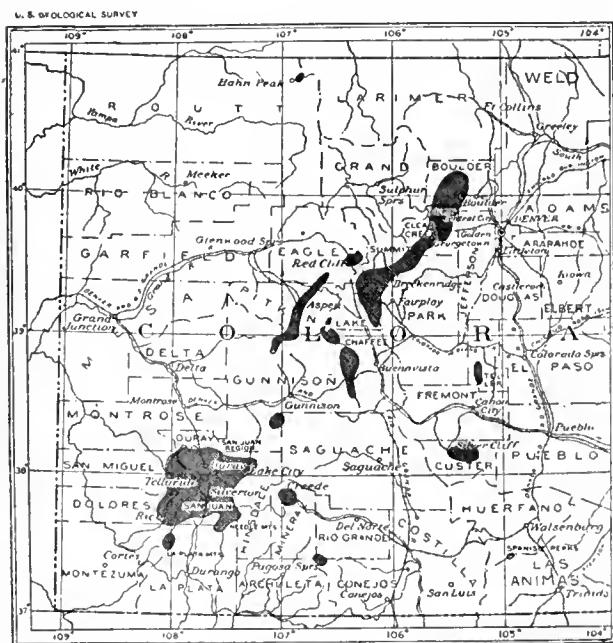

(Special Correspondence.)—The water in the Dutch

mine, at Quartz, has been lowered 250 ft. since the work of unwatering to bottom began. It is estimated that the pumps must continue in operation for at least two months longer to finish the work. It is the intention to open much new ground in the lower portion of the mine by driving. Work has for a long time been confined to the upper levels of the property. The Columbia Basin mine, a deep gravel property, situated near Columbia, is to be reopened for the resumption of mining work. During the last period of activities at the property, a fine surface equipment was put in and extensive development work was done. Preparations are being made by John Segale to begin mining operations in the bed of the Tuolumne river above the Clio mine. The stream will be diverted from its natural course by constructing a dam and large ditch. It is expected that the shaft at the Experimental mine, above Columbia, will cut the vein within a few days, when driving will begin. It has almost reached the depth of 300 ft. A mill-test is to be made of ore from the Sonnet mine, in the Columbia district. A large new pump has been installed at the Shawmut mine at Jack-sonville.

Sonora, June 28.

COLORADO

Colorado is the most important coal-producing state west of the Mississippi river, and ranks seventh among all the states. The coal mined in 1912 was 10,977,824 short tons, an increase of 820,441 tons over 1911, according to

COLORADO. MINERAL AREAS IN BLACK. COAL IN SOUTHEAST.

E. W. Parker, of the United States Geological Survey. The value increased from \$14,747,764 to \$16,345,336. The total area underlain by coal in Colorado is estimated at 17,130 sq. miles, and about 60% of that entire area is believed to contain coal that is workable under present conditions. The state contains areas embracing over 4000 sq. miles, about which little is known, but which may contain workable coal, and nearly 3000 sq. miles in which the coal lies under heavy cover and is therefore not workable at present. In point of production, the most important area is the Trinidad field, underlying considerable portions of Huerfano and Las Animas counties, which in its southern extension into New Mexico as the Raton field is also the most important producer in that state. The coal of this field is a high-grade coking coal, probably the best coal of that grade in the Rocky Mountain states.

THE SAN JUAN

During May the Tomboy mill worked 29 days, crushing 12,000 tons of ore yielding \$25,000 and \$59,000 from 1550 tons of concentrate shipped. The profit amounted to \$35,000.

IDAHO

BONNER COUNTY

The Buckhorn Mining Co. is building a 5-stamp mill on the east fork of Deer creek. The development of this mine consists of 2000 ft. of adits. Assays run from \$16 to \$40 per ton. A wagon-road has been constructed to this mine and the crew employed at the mine consists of 18 men under the charge of William Johnson. It is expected that there will be water enough to be used to run the mill when ready for operations.

CLEARWATER COUNTY

A gold nugget weighing 19.6 oz. and worth \$290 was found by G. V. Friedman at his placer claim on Snake creek. The gravel here averages 60 to 70c. per yard, and the nugget was found at a depth of 10 feet.

IDAHO COUNTY

The Moscow mine is changing hands. Mill equipment is of a crude type to treat the low-grade ore mined.

SHOSHONE COUNTY

The Big Creek Leasing Co. has been incorporated at Kellogg with a capital of 5000 shares of \$10 each. Its object is principally leasing work. The Interstate and Callahan mines are now connected by a 5400-ft. tunnel, which is being extended 2000 ft. to the Amazon-Manhattan. This property is under option to the Interstate for \$160,000. A 300-ton mill is operated by the latter. Ore from the mine is conveyed to the plant by an aerial tramway of 1000-ton daily capacity. The orebodies in the various properties are rich in lead, silver, and zinc. The silver yields as high as 50 oz. per ton, 76% lead, and 59.7% in zinc, and the new mill is making an extraction of 95% of the mineral content.

MONTANA

The production of coal in Montana in 1912 was 3,043,495 short tons, valued at \$5,342,168, according to E. W. Parker, of the United States Geological Survey. This is the first time that the output of the state has passed 3,000,000 tons. The coalfields of Montana are widely scattered and their output ranges in quality from lignite to a bituminous coal of fair grade. Nearly all of the eastern third of Great Plains portion of the state is underlain by lignite and low-grade sub-bituminous coal. Toward the mountainous district the coals pass into high-grade sub-bituminous and true bituminous coals. These occur for the most part in relatively small and much scattered areas. In the valley region of the western part of the state the coals grade again into lignite, but unlike those of the eastern part, they are widely scattered and at present are not of economic importance.

LINCOLN COUNTY

(Special Correspondence.)—J. J. Hibbard and P. S. Rose, who recently leased the Peterson-Bergstrom gold mine about 25 miles south of Libby, have received returns from a mill-test of the ore which they say is very satisfactory. The test showed that 90% of the contents could be saved. The ore vein carries on an average gold to about \$20 per ton. It is the intention of the lessees to erect a stamp-mill and concentrator on the property.

Libby, June 22.

MISSOULA COUNTY

The Iron Mask Mining Co. has 10 mining claims, two millsites and two water rights, in the Spring Gulch district, near Keystone. Mining is mostly done by adits, and has been under way since the beginning of 1907. It is intended to erect a mill in the near future.

SILVERBOW COUNTY

(Special Correspondence.)—The new mill of the St. Louis Mining Co. has been placed in operation. It has a capacity of 200 tons per day, and, according to information given out, it is giving general satisfaction. It is being operated by electricity, and those in charge say that this power is much more satisfactory than steam. The Butte-Alex Scott, during the year ended June 1, earned over \$81,000 net as compared with \$19,000 for the same period last year.

The mine is the best paying independent property in the district at the present time, and as depth is being attained, the mine is making a much better showing than ever before. A. B. Wolvin, of the Butte & Duluth company, says that he will have his enlarged leaching plant in operation within the next two months, and at the present time he is treating 100 tons of 4% copper ore per day, from which he is receiving a return of 98% pure copper. Mr. Wolvin says that when the enlarged plant is completed, he will handle 500 tons of ore per day. The force of miners has been increased for the purpose of getting out a large supply of ore. According to reports given out by the Davis-Daly people, the Colorado mine is fast becoming a producing property. The Hesperus orebody, cut on the 1400-ft. level over eight weeks ago, was picked up a few days ago in No. 2 cross-cut, 125 ft. farther east than where the orebody originally was found. Development has disclosed an orebody 14 ft. in width, averaging about 4% copper with some silver. The Hesperus orebody has been proved for a distance of 325 ft., 200 ft. of which, west from No. 1 cross-cut, shows a shoot, the average width of which is 17 feet.

Butte, June 28.

During the first three weeks of June, the Butte & Superior mill averaged 650 tons of ore daily, with 1½ sections in commission. The concentrate assayed 49% zinc, and recovery was 89 per cent.

The Belmont shaft at the Butte is down 2400 ft., and connections have been made with other mines of the Anaconda group. Underground wiring for electric traction is underway. A 5000-ton ore-bin is being built and will be provided with modern appliances for loading ore into cars for transport to the Washoe smelter. At the Butte & Zenith 500-ft. level cross-cut, a well defined vein has been cut. An electric pump has been installed, and the electric hoist is ready for operation.

NEVADA

CLARK COUNTY

(Special Correspondence.)—The Eldorado mining district, of this county, better known as the Eldorado Cañon area, is enjoying a revival of activity. From 25 to 30 years ago its surface ores produced several millions of dollars. The district was practically abandoned seven years ago. G. A. Duncan has been developing a large group of prospects, which he afterward purchased, and has been urging the importance of the district on others who were seeking mines. Four good mining companies are now pushing development work on as many different groups of claims, with good cause for encouragement.

Nelson, June 27.

ESMERALDA COUNTY

On July 4 there will be drilling contests at Goldfield. Prizes for double and single work will be \$500 and \$200, and \$150 and \$75, respectively, for first and second places.

EUREKA COUNTY

(Special Correspondence.)—The work on the Buckhorn mill is going ahead at a good rate. The framework, is up for the crushing plant, the tube-mill foundations are in, and the concrete work for the cyanide plant is about completed. The haulage adit has been connected with the mine workings, and about 15 miles of the poles for the transmission line are already up. The power plant is situated at Beowawe, on the main line of the Southern Pacific, some 30 miles north of Buckhorn.

Buckhorn, June 28.

HUMBOLDT COUNTY

Sulphide ore has been opened at a depth of 200 ft. in the Big Four mine, Rochester. The vein is 9 ft. wide, averaging \$35 per ton. Diamond-drilling will be done at the Seven Troughs Coalition mine.

LINCOLN COUNTY

The Prince Consolidated is shipping 200 tons of ore per day. Tailing shipments from Bullionville to the Toelee smelter have been curtailed. It is stated that there is 600 ft. of unprospected ground in Prince territory, between the south end of its workings and the Virginia-Louise

property, which has proved the Prince iron-ore deposits as large and valuable as in the older mine.

MINERAL COUNTY

Cinnabar has been opened near Mina, and samples return 6.5% mercury. The Goldfield Consolidated Mines Co. has recently ordered from the General Electric Co. a new 600-hp. induction motor.

NYE COUNTY

(Special Correspondence.)—G. A. Duncan, of Nelson, Nevada, has sold his five patents pertaining to the treatment of slime in cyanide mills. As the purchase was made by a consolidation of the milling companies of Tonopah and Goldfield, the active agent in the transaction being Albert Burch, manager of the Wingfield interests, it is possible that questions as to rights and royalties which were supposed to be settled by the court decision in the Moore-Butters case, may be reopened. In an article published in the *Mining and Scientific Press* on June 6, 1908, the statement was made that Mr. Duncan was the first to use and patent the internal water-pressure for tailing discharge, and the perforated-pipe filter-cell frame, which features displaced the internal air-pressure for tailing discharge, and the wooden cell-frame, used by Mr. Moore.

Tonopah, June 27.

STOREY COUNTY

Comstock mining companies report the following during the week ended June 28: The pumps at the C. & C. shaft worked without trouble, and on the 2500-ft. level the north drift has been repaired a total of 865 ft. to date. The Ophir 2500-ft. level raise produced 96 tons of \$35.53 ore. The cyanide plant treated 549 tons of tailing, and bullion valued at \$5400 was shipped. The Mexican mill treated 657 tons of Mexican ore, averaging \$47.70 per ton, with 93% extraction.

WASHOE COUNTY

(Special Correspondence.)—The Granite Hill copper mine, 14 miles northwest of Reno, operated by the Warner-Nelson Co., has shipped 51 tons of ore averaging 15% copper and \$15 per ton in gold and silver.

Reno, June 23.

WHITE PINE COUNTY

Work to be undertaken by the newly formed Consolidated Copper Mines Co., at Ely, includes the following: Development to block out more ore in all the properties concerned; the remodeling of the Giroux mill at Kimberly for experimental purposes, especially as to the adaptation of the oil-flotation process to recovering the metals from low-grade ores; unwatering of the big Giroux shaft, and further development of the Alpha ore deposits, and, possibly, the sinking of a deep working-shaft on the Chairman group.

OREGON

BAKER COUNTY

A gold nugget weighing 80.4 oz. was found last week by Armstrong & Stuart at their placer claim, three miles from Galena. The district is fairly active. The diamond-drill in operation since spring, prospecting for dredging ground, was taken last week to the Granite district. The bench land near Sumpter has been drilled, and it is reported that another dredge will be erected there. The Sumpter dredge is having new lips fitted to the buckets, and is also operating the plant for about 12 hours per day.

UTAH

JUAN COUNTY

The report of the Beck Tunnel Consolidated Mining Co. for the year ended June 1, 1913, gives the following information:

Development feet	1,252
Ore production, tons	6,419
Gold content, ounces	785
Silver, ounces	110,890
Lead, pounds	1,880,706
Value	\$72,488
Total income	94,500
Expenses	94,500

SALT LAKE COUNTY

The long tunnel of the Utah Metal Mining Co. was completed on June 23, according to information from E. P. Jennings. This drive has been made through the mountains from the Middle cañon side to the Bingham side of the range, and is 11,474 ft. in length. It took 2½ years to complete. With the single exception of the Ontario drain tunnel at Park City, which is 3½ miles in length, this is the longest adit used for mining purposes in the state.

WASHINGTON

FERRY COUNTY

The Surprise mine produced 1160 tons of \$12 to \$20 ore during the first half of June. This comes from stopes on the 400, 500, and 700-ft. levels. The ore is sent to the Greenwood, British Columbia, smelter.

OKANOGAN COUNTY

(Special Correspondence.)—Engineers from the Trail and the British Columbia Copper Co.'s smelter, at Phoenix, British Columbia, have been examining the Copper World and Copper World Extension mines, on Palmer mountain. Republic, June 27.

STEVENS COUNTY

A cross-cut in the Butte-Chewelah property, near Chewelah, has cut a 20-ft. vein at a depth of 100 ft. About 5 ft. of the shoot carries gray copper and some silver. A winze is to be sunk 300 feet.

(Special Correspondence.)—The United Copper Co. is installing four new batteries, of three stamps each, and will double the capacity of the mill. Holes have been dug, and the poles have been distributed for the transmission line from Myers Falls.

Chewelah, June 26.

CANADA

ALBERTA

(Special Correspondence.)—The Pelican Portage gasfield and other localities in central Alberta are being examined for the City of Edmonton by L. G. Huntley, of the Associated Geological Engineers of Pittsburgh, Pennsylvania.

Edmonton, June 23.

BRITISH COLUMBIA

(Special Correspondence.)—Ore production for the third week in June in the Kootenai and Boundary districts is reported as being 47,212 tons, making a total for the year of 1,207,712 tons. One hundred thousand dollars will be spent by the British Columbia Copper Co. in the erection of a concentrator at the Voight properties, near Princeton, according to a report from Greenwood. The action is prompted by results obtained from diamond-drilling and other investigations during the past two years.

Spokane, June 27.

The Granby company has acquired the claims of Moulton, Hartley, and associates near Portland Canal. The ore opened will be used for fluxing. The British Columbia Copper Co. is employing 110 men on Copper mountain, near Princeton. Recently the Lucky Jim shipped from the Slocan 17 cars of zinc ore to the United States, upon which the duty amounted to \$17,000, and may shut down until the tariff is lowered. The streak of high-grade ore in the Dynamo claim has widened to six inches. During the last six years Partman Bros. have expended \$20,000 developing this property.

In the Flathead valley, at the junction of Sage creek and the Flathead river, on the British Columbia side of the line, a company composed of Victoria and Vancouver capitalists is now engaged in drilling a well for oil. A contract has been given to California oil-well drillers to sink several holes to a depth of 2700 ft., and, if necessary, 4000 ft. The first well is already down several hundred feet. During the past 100 years or more, Indians have skimmed oil from the seepages on the surface.

KOREA

(Special Correspondence.)—During April, 240 stamps of the Oriental Consolidated Mining Co.'s mills worked 26 days and treated 26,236 tons of ore, yielding \$163,312.

Operating costs were \$85,280, development and improvements, \$2815, leaving a profit of \$75,716. The Kuk San

TAROWIE MILL OF ORIENTAL CONSOLIDATED COMPANY.

Dong mill was shut down during the past month on account of shortage of ore.

New York, June 23.

MEXICO

MEXICO

During May the 40-stamp mill of the Mexico Mines of El Oro worked 30 days, treating 13,400 tons of ore yielding \$138,530. The profit was \$82,780. The 100-stamp mill of El Oro Mining & Railway Co. worked 30 days, treating 23,830 tons of ore and 14,190 tons of tailing, yielding \$227,360. The total profit was \$92,950, including \$5680 from the railway.

SONORA

(Special Correspondence.)—The Calumet & Sonora of Cananea Mining Co., whose property is about two miles northwest of Cananea, and which recently resumed operations after being shut down for almost three months, is now working with practically a full force. One hundred and sixty men are now being employed. Before the shut-down but 60 were working. In fact, conditions are better at the property than they have been for some months, and the production is at the rate of 7000 tons of ore per month. Both the wet and dry mills are again working, two shifts being employed, and it may be only a short time before the mills are working 24 hours each. The ores being handled at present come from the 400 and 500-ft. levels. The new crusher and picking belt which were installed early in the year are giving good results. Fifty per cent of the material passing over the belts is thrown out as waste. W. H. Tangye, the superintendent, reports that development work is being done only on the 400-ft. level, where results are highly satisfactory. The management states that, in the near future, operations will be conducted at full capacity, as a large orebody which was found shortly before the shut-down, three months ago, promises to furnish sufficient ore to run the plant for an indefinite time. An output of 40 tons per day, which will average \$30, is figured. This gives a monthly earning of \$36,000 at an expense of \$12,000. The company has shipped its concentrate which was stored awaiting the end of El Paso smelter's labor trouble. There were six cars which netted \$12,000.

Cananea, June 28.

TRANSVAAL

A strike has broken out in the Rand district which threatens to tie up the entire gold-mining industry of South Africa. The dispute arose from a simple question about working hours in the new Kleinfontein mines, and from there gradually spread until the situation became so serious that troops were called out to protect property. The leaders of the unions have called a general strike, and the men have promised to respond. The closing also of some coal mines has aggravated the situation, and the railway employees threaten to come out. Meanwhile, the electricians appear inclined to shut down the power stations, which have therefore been occupied by the military.

Schools and Societies

THE UNIVERSITY OF WISCONSIN held its sixtieth commencement on June 18, Charles R. Van Hise delivering the address.

THE UNIVERSITY OF CALIFORNIA, at Berkeley, opened its summer school on June 23, with over 2000 students, and will continue for about six weeks.

A PARTY of seventeen students of mining from the Case School of Applied Science, Cleveland, Ohio, has been inspecting the mines and mills of the Coeur d'Alene. They are also doing some practical work.

THE MASSACHUSETTS 'TECH' held its commencement on June 10, and about 300 students received degrees, of which 21 received the degree M.S., and 269 the degree B.S. Chas. Ransom Hill presented a thesis, the title of which was 'Cyanidation of Low-Grade Silver Ore from Utah.'

THE UNIVERSITY OF ILLINOIS summer session opened on June 16, and will close August 16. Courses offered are arranged primarily for the needs of teachers, principals, and superintendents. Many of the regular university instructors will offer instruction during this special summer session.

The UNIVERSITY OF VIRGINIA, at Charlottesville, held its commencement exercises, finishing the eighty-eighth consecutive session, during the week ended June 21. There were 116 graduates. A gift providing for 10 scholarships of \$300, or 5 of \$600, per annum, to be awarded to young Virginians was announced.

HARVARD UNIVERSITY held its annual commencement starting June 14. Work is practically finished on the new Coolidge laboratory for the department of chemistry. The new building, which will be in active use with the opening of college in the fall, is a memorial to T. Jefferson Coolidge, '84, whose family subscribed \$50,000 for its construction.

ANNOUNCEMENT is made that the first work in which co-operation between the Massachusetts Institute of Technology and Harvard University is to be effected has been outlined, and the confirmatory votes have been cast by the members of the two corporations. It is an arrangement whereby the students in public health, biology, and sanitary matters may have the benefits of corresponding courses.

COLUMBIA UNIVERSITY will have about 4000 students attending the six weeks' summer school which opens early in July. There are to be 243 instructors and 38 assistants. Students planning to spend the summer or the remainder of the year in Germany have been aided by a new department in the Deutsches Haus. It is called the Bureau of Academic Information, and is open daily, except Saturday, from 9 until 5 o'clock. It contains the announcements of the various German universities and scientific schools, as well as many books and pamphlets pertaining to higher education. Under the joint auspices of Columbia's Maison Française and the Paris Sorbonne, a students' tour of France is also planned for the summer.

Arrangements for the twenty-fourth general meeting of the AMERICAN ELECTRO-CHEMICAL SOCIETY, to be held at Denver, September 9 to 11, are progressing well. Offers of papers for the meeting have increased to twenty-one; four papers are already at hand, and one has been distributed. Several more will be ready for distribution with the July *Bulletin*. Those having papers to present at this meeting should bear in mind that in order for them to be printed and distributed in advance of the meeting, the manuscript should reach the secretary not later than July 15. If the title of the paper has not been sent in, it should be as soon as possible. Joseph W. Richards is secretary, at the Lehigh University, South Bethlehem, Pennsylvania.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

J. W. FINCH is in the East.

W. A. HALL has gone to Europe.

THOMAS F. COLE is in New York.

JOSEPH W. RICHARDS is in France.

JAMES DOUGLAS has gone to Europe.

BARTON SEWALL has sailed for Europe.

P. D. BURTT has gone to Seward, Alaska.

F. G. COTTRELL was in New York last week.

H. F. WIERUM is expected in San Francisco.

THOMAS T. READ was in Boston early in the week.

F. C. ALSDORF is visiting Cobalt and neighboring districts.

A. B. WILLARD is president of the Republic Mines Corporation.

THOMAS JAY is superintendent at the Frisco mine, Mullan, Idaho.

HERBERT C. ENOS is now at Edificio La Mutua, No. 200, Mexico, D. F.

HENRY BISHOP is superintendent at the Last Chance mine, Coeur d'Alene district.

HARRY J. WOLF has been examining a property in Calaveras county, California.

W. L. Anderson is local manager for the Mother Lode Sheep Creek Mining Company.

C. F. RAND and BRADLEY STOUGHTON attended the recent meeting of the American Society for Testing Materials at Atlantic City.

T. R. WOODBRIDGE, who has been visiting sampling works in the interest of the U. S. Bureau of Mines, was in San Francisco this week.

J. A. HOLMES and a party of engineers from the U. S. Bureau of Mines will sail from Seattle on the *Admiral Sampson* today to investigate the Matanuska coalfields.

H. FOSTER BAIN will leave for Denver and the East, Tuesday. He will attend the International Geological Congress at Toronto in August as a representative of the American Institute of Mining Engineers.

Japanese Coal Situation

The Imperial Government of Japan has placed an order for about 150,000 tons of Fushun coal for the railways for the current year. The aggregate annual consumption by the whole of the service is figured about 1,200,000 tons per year, and Fushun coal now comes in for the supply of one-eighth of the total consumption. The appearance of this coal on the field at home little disconcerts the suppliers of home coals. Such is stated to be the case by a good authority, who ascribes it to the rapid growth of industrial enterprises all over Japan. The demand for coal is rising year by year, and the import of Fushun coal in considerable quantities is no longer looked upon as a trespass upon the legitimate market for home coals. Two shafts have been sunk on Shimoputago islet, Japan, the work marking an important development of the Takashima collieries, which are owned by the Mitsu Bishi Co. It is estimated that 34,000 tons of coal will be obtained from the new shafts this year and that a monthly output of 30,000 tons will be possible when the preparatory work is complete. The colliery will be known at Futagoshima. The coalfield tapped by the shafts is called Nakanoshima and contains, according to experts, 11,520,000 tons of coal. The yield is estimated to last 34 years. Another coalfield lies between Nakanoshima and Takashima and will be reached in the near future. Its area is far greater than the dimensions quoted above and 70 years is estimated as necessary to exhaust the reserves of both fields. The daily outputs of Takashima and Hashima mines, which up to now have supplied all the famous Takashima coal, are about 300 tons and 500 tons, respectively.

New York Metal Market Review

Copper declined steadily in June, the concessions being made principally by second-hands; various influences both at home and abroad being held accountable, in addition to lack of demand. Lead, despite the absence of any really good demand, held up well, but the course of the metal in London and the consequent effect on the New York market was disappointing. Spelter was uniformly dull and declined steadily. Antimony was without any interesting feature beyond the continuance of low prices. The demand for tin was not heavy, prices declined, and London, always irregular, was unusually erratic. Aluminum was lower at the end of the month and much affected by tariff possibilities.

- COPPER

The Waterbury average for May was 15.87½c. The early days of June were almost completely devoid of demand, not even re-sale lots of electrolytic at around 15.25c. cash, New York, inducing consumers to enter the market. At no time was there much betterment. When the month opened, the large agencies were holding to their prices of 15.75c. cash, New York, for electrolytic and 15.87½ to 16c. for Lake, with the latter scarce for early delivery. At this time it was freely admitted that consuming mills were receiving fewer orders, though they were busy on those previously booked. In London the market weakened in the early days of June. About June 7 there were some sales of electrolytic by second-hands at 15.37½c. cash, 30 days delivered, equal to 15.25c. cash, New York. London continued to decline. In the second week of the month there were additional sales of electrolytic, also by second-hands, who accepted substantial concessions according to report. One of the large agencies did not deny on June 18 that its price abroad had been reduced to 15c. Many rumors were rife in the second week of the month, and the situation was rather unsettled in consequence. An added cause of uneasiness was a strike at the Laurel Hill, L. I., refinery of the Nichols Copper Co., which to some extent curtailed production. In the third quarter of June the quiet continued. Lake copper of a good grade, but not equal to prime Lake, was offered at 15c. cash, New York, but no takers came forward. For actual prime Lake, an offer of 14.75c. was made, but holders would not sell at this figure. In fact, practically no business was stirring, and producers saw no incentive for reducing their prices. Some re-sale lots were sold at 14.50c. cash, New York, but the quantities were not great. Four reasons were advanced for the quiet which prevailed: the fact that consumers were comfortably well supplied for their June needs, the falling off in new business, fears of tariff changes, and unsettled finances abroad. Toward the latter part of the month the American Brass Co. reduced the price of sheet copper and copper bottoms one cent, making the new base price for sheets 20c. and that for bottoms 26c. per pound. Near the end of June the price of electrolytic copper was weak at 14.50c., and that of Lake almost as weak at 15c. In Lake, especially, prices were largely nominal. Up to June 27 exports amounted to 23,858 tons.

LEAD

In the latter part of May there was a little flurry in lead, though no buying that might be called heavy. Early in June interest died out, but the metal remained firm at 4.35c. New York and 4.20c. St. Louis. Approaching the middle of the month, an interesting situation developed because of the price advances in London. The foreign quotation June 11 was £20 7s. 6d, equal to 4.36c. New York. It was foreseen that if the foreign price went up a few points more to cover freight to London, English buyers could come to the New York market. A week later, June 18, the London price was £21, equal to 4.48c. New York. Subtracting 15c. per 100 lb. for freight left 4.33c., the price at which London could buy in New York. This was within two points of the New York price. The situation greatly strengthened the market, although New York quotations did not advance. Still another supporting influence was a fire which damaged the plant of the St. Joseph Lead Co., Herculaneum, Missouri, and which interfered with deliveries by that Company. The situation resulted in 4.22½c. St.

Louis being asked by some interests. Expectations of any large business from abroad were quashed when it developed that the high London price was the outcome of a corner not strong enough to stand. The foreign price declined and the incident was closed. Domestic consumers at the end of the month were buying only in a hand to mouth fashion.

SPELTER

The market at the beginning of June was about 5.30 New York and 5.15 St. Louis, very quiet and weak. It was reported that the demand of the galvanizers had fallen off. As the month progressed there were repeated declines, and the only demand that might be called even fair was for future metal. Toward the end of June the metal was quoted at around 5.16c. New York and 4.95 St. Louis and sellers were not inclined to press sales at these prices. It came to light that about 2000 lb. of spelter which had been smelted in bond from Mexican ore had been shipped to Europe. In the last few days of the month a little better demand developed and better buying was expected to soon materialize because of the fact that consumers had been out of the market so long that their stocks were low.

ANTIMONY

Throughout the month antimony was dull and without sufficient business to fully test prices. Hallett's was quoted at from 8.15 to 8.25c.; Cookson's at from 8.60 to 8.70c; and Chinese and Hungarian grades at from 7.50 to 7.75c.

TIN

The month opened quietly following the heavy buying in the last days of May referred to in the last report. The buying in that movement was caused by heavy unloading by one London house. Early in June the price dropped to 46.60c. New York, a decline of several points under what purchasers had paid a few days previously, and they naturally were much disappointed. On June 9 about 300 tons was sold for delivery in various months, the spot price being 45.37½ to 45.50c. At this time the supply was pretty well concentrated in a few hands. London had shown a persistent declining tendency. Toward the middle of June the market was very dull, so much so that 100 tons of Banca tin was re-shipped to London. Straits tin is always preferred in the New York market, though Banca is acceptable in times of shortage. The London market was very erratic in the third and last quarter of the month. June 17 London declined £3, which was attributed to financial conditions abroad unfavorable to speculation and to the poor demand from this country. On June 18 the London price touched £203 5s. for spot, which up to that day was the low point of this year, but there was a rally after this low figure. In the last part of the month the market was very dull, and for much the same reasons as were mentioned in the copper report. In London there was much liquidation, forced, it is understood, by the withdrawal of loans to Vienna operators by the bank which was financing them. The result was a decline of £12 in four days, which was followed by a recovery of £6 in two days. On June 23, spot tin was down to £193 in London. On June 27 the metal suffered another decline in London, falling £3 10s., the cause being reports from the United States that tin-plate mills might curtail consumption. These reports were not borne out by statements which followed here. The tendency throughout the month was a declining one, the month opening at 46.60c. and prices standing at 44.10c. on June 26. Arrivals up to June 27 totaled 3000 tons and there was afloat 875 tons.

ALUMINUM

In June aluminum declined by easy stages from 25-25.50 to 23.50-24.50c. The most interesting feature of the month was the proposal of the United States Senate to fix the duty on aluminum ingots at a flat rate of 2c. per pound, instead of the duty of 25% ad valorem proposed by the Underwood bill as passed by the House of Representatives. The present rate on ingots is 7c. per pound. Authorities have pointed out that the cost of foreign aluminum is at present 18½ to 19c. per pound c.i.f. New York, which, with a 2c. duty would make it 20½ to 21c. per pound. This compares with the present price of 23.50 to 24.50c. to the disadvantage of the American product, as can be seen.

The Metal Markets

LOCAL METAL PRICES

San Francisco is not a primary market for the common metals except quicksilver. The prices quoted below therefore represent sales of small lots and are not such as an ore-producer could expect to realize. Ore contracts usually call for settlement on the basis of Eastern prices, less freight and treatment charges. The prices quoted are in cents per pound, except in the case of quicksilver, which is quoted in dollars per flask of 75 pounds.

San Francisco, July 3.		
Antimony.....	12-12½c	Quicksilver (flask).....\$41
Electrolytic Copper.....	16-16½c	Tin.....50-51½c
Pig Lead.....	4.60-5.55c	Spelter.....7-7½c
Zinc dust, 1400 lb. casks, per 100 lb., small lots \$9.50-9.75; large \$7.50-8.50		

EASTERN METAL MARKET
(By wire from New York.)

NEW YORK, July 2.—Copper remains unchanged, though small lots have been sold at a slight concession. In general, buyers are waiting, and the Copper Producers' figures are anticipated with much interest. Lead is steady, the fire at Herculeaneum having made no impress on the market. Spelter is beginning to show the effect of curtailment of production, and prices are firm, though no higher.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

June	6.88	5.00	Dec.	7.09

L. Vogelstein, in a trade letter dated June 27, points out that consumption of spelter has, as yet, been but little reduced. It is the decrease in future orders for iron, steel, and brass goods that makes buyers nervous and which has affected prices. The Senate proposes to raise the tariff from 10 to 15%, and on ores from 10 to 12½%. Assuming that spelter abroad goes as low as £20, and that the Senate rates stand, 5.25c. would be the lowest New York price for imported spelter, and this would constitute no menace to American producers. It is well known that there has been insufficient spread between prices of ore and metal, and that new works have been building. Present conditions discourage the builders from firing up, and mines are closing. It is worth remembering, however, that the present financial storm has been foreseen and largely discounted. While, therefore, immediate prices may be low, it may be but a short time before good conditions return.

COPPER

Quotations on copper as published in this column represent average wholesale transactions on the New York market and refer to electrolytic copper. Lake copper commands normally from 1-5 to 1-4c. per lb. more. Prices are in cents per pound.

The fortnightly statistics of copper show that the European stocks, including Hamburg and Rotterdam, on June 30 decreased 1727 tons, while copper supplies afloat decreased 50 tons, making a total decrease in the visible supply of 1777 tons to 38,199 tons, as compared with 39,973 tons on June 14 last.

QUICKSILVER

The primary market for quicksilver is San Francisco, California, being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher

price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

Dividends

THE Shattuck-Arizona Copper Co. has declared a dividend of 50c. per share, making \$4 to date. During 1912 no payments were made.

THE Ahmeek Mining Co. has declared a quarterly dividend of \$5 per share, as against \$7 paid in the two previous distributions.

THE Bunker Hill & Sullivan Mining & Concentrating Co., on July 3, paid dividend No. 190, amounting to \$65,400. This makes a total to date of \$14,369,550.

THE Federal Mining & Smelting Co. will pay a dividend of 75c. per share, on July 15, on the common stock. This is the first payment on this stock since January 1909. On the same date, the preferred stock will be paid 87½c. per share, the second during 1913. Total dividends declared to date amount to \$10,399,750.

THE Consolidated Mining & Smelting Co., operating a smelter and a number of mining properties in British Columbia, paid a semi-annual dividend of \$220,000, on July 5. The disbursement is based on a rate of 8% per year on the issued capitalization, and will bring the total payments of the company to \$1,234,061.

IN July a total of \$263,419,305 will be paid to investors representing dividend and interest disbursements by railroad, industrial, and traction corporations, banks and trust companies, the national government, and New York City. This compares with \$253,267,992 last year. This month the sum of \$95,885,055 will be paid to stockholders in the way of dividends, or an increase of \$3,430,263.

THE Abangarez Gold Fields Co. of Costa Rica reports the following results of operations at its mines:

Joplin Ore Market

At the beginning of July, zinc sulphide ores brought \$39 to \$43 per ton, assay basis of 60% metallic zinc, and spelter at East St. Louis was quoted at \$5 per cwt. These figures compared with those of the corresponding period of 1912 are discouraging, but conditions throughout the district nevertheless are fairly good. At this time a year ago zinc sulphide ores brought \$54 to \$55, basis, with better grades selling for \$61, and spelter brought \$7. Shipments are less than 5000 tons per week, and the output is possibly a few hundred tons in excess of this, as a number of operators are holding for better prices. This indicates a gradual increase in the surplus reserves, which are now about 4500 tons. Calamine brings \$20 to \$21 per ton, assay basis 40% metallic zinc. Lead ore is unchanged at \$52.50 per ton, 80% metallic lead.

Coal Mining in China and Japan

There is a colliery at Huashihling, northeast of Changchun, with a coal seam said to 15 ft. thick. At present about 13 tons is produced daily. With the use of modern machinery the daily output will easily be considerably increased. The Chinese tax collector at Changchun resigned his office recently to assume management of the colliery. He has paid about \$37,500 to the concessionaire as the price of the property and is said to have a similar amount to invest in the mine. Recent coal production of the Kailan mining administration's mines was as follows:

	Output, tons.	Sales, tons.
Week ended March 22	28,656	44,685
Week ended March 29	39,686	40,352
Week ended April 5	39,932	40,404
Week ended April 12	36,101	50,597

NORWAY'S ore production in 1912 was as follows: pyrite, 43,000 tons; iron, Norway and Sweden, 400,000 and 2,800,000 tons respectively; and nickel ore, about 250,000 tons. The Sultjelma copper mine produced 149,600 tons of ore, yielding 11,500 tons concentrate by the Elmore process. There are 11 Elmore machines in operation. A Wedge roasting furnace was installed to deal with the Elmore concentrate. The Sydvaranger Iron Ore Co. will soon be in a position to produce 650,000 tons per annum. The Evje nickel mine produced 240,000 tons of ore, and the refinery produced 400 tons of nickel and 200 tons of copper.

PIG-IRON PRODUCTION of Germany during 1912 was 17,852,571 metric tons.

*Extra charge for packing nitric acid for shipment to conform to regulations.

Recent Metallurgical Patents on the Rand

REGULATING UNDERFLOW FROM CONE SAND CLASSIFIERS

The application of Charles William Dowsett is for the purpose of providing automatic means for regulating the underflow from cone sand classifiers. An outlet valve at the underflow aperture is made to open when the frictional engagement of the moving sand overbalances a weighted level which again comes into operation to close such valve when the sand is below a predetermined level so that the vertical surface supplied for the frictional engagement presents a smaller area of contact.

REGULATING UNDERFLOW OF CLASSIFYING CONES

The application of William Arthur Caldecott refers to the means for regulating automatically the underflow of a classifying cone or similar apparatus, the main part consisting of a buoyant body or float which actuates a valve or equivalent device placed at or near the outlet of the cone, the said body of float falling or rising according to the depth of settled solids increases or decreases inside the cone and thus automatically opening or closing the outlet. This apparatus is used in combination or otherwise with the diaphragm forming the subject matter of patent No. 231 of 1908.

TUBE-MILL DISCHARGE

The application of William Calder has reference to the discharge of ground pulp from tube-mills and consists of a perforated plate through which the pulp enters a lift chamber having means, such as radial arms, to elevate the pulp and discharge it into the discharge trunnion of the mill. Its usefulness lies in the free and rapid discharge of comminuted ore from the mill, giving the effect of a peripheral discharge.

Barytes Production, 1912

The production of crude barytes in the United States in 1912, according to figures compiled by J. M. Hill, of the United States Geological Survey, was 37,478 short tons, valued at \$153,313. Compared with the production of the preceding year this was a decrease of 967 tons in quantity, but an increase of \$30,521 in value, the average price per ton reported to the Survey in 1912 being \$4.09, compared with \$3.19 for 1911. At the close of 1912 there were 6262 short tons of crude barytes unsold at the mines. There was also 29,865 tons of barytes imported, having a value of \$79,315, and \$376,017 worth of barium salts, including artificial barium carbonate and blanc fixe.

The greater part of the barytes produced in the United States is used as a pigment in the manufacture of mixed paints. It is also used in the manufacture of lithopone, a white pigment. Other uses for the mineral are in the manufacture of rubber, wall paper, asbestos cement, and poker chips, and in tanning leather. A use of barytes reported from Italy is in the manufacture of gorgonzola cheese. The cheese receives a covering in the form of a thick heavy crust of the finely ground material which has the property of affording just sufficient protection from aeration.

Chilean Sale of Nitrate Lands

A decree has been issued fixing November 17, 1913, as the date of the next public sale by auction of nitrate lands belonging to the Government. The lands to be sold are known as the Santa Laura de Wendel property, and it is estimated to contain 15,000,000 metric quintals of nitrate (metric quintal, 220.46 lb.). It is situated in the province of Tarapaca. The Government reserves the right to divide the property into two lots if desired. The sale will be held before the Junta de Almoneda in Santiago under the usual terms and conditions.—*Consular Report*.

ST. JOHN DEL REY mine, Brazil, produced gold valued at \$153,000 from about 14,000 tons in May.

POTASH PRODUCTION of German mines during 1912 was 4,736,105 tons.

Decisions Relating to Mining

Specially reported for the MINING AND SCIENTIFIC PRESS.

OIL LEASE—TREATED AS AN OPTION

An oil and gas lease was held to be a unilateral contract which did not bind the lessor unless certain conditions were performed by the lessee. If the lessee failed to perform such conditions within the time prescribed, then the lease was to be treated as a forfeited option and the lessor released from all obligations thereunder.

Witherspoon v. Staley (Texas), 156 Southwestern, 557. March 12, 1913.

OIL PLACERS—INJUNCTION DENIED

In an action to determine the ownership and right to possession of certain mining claims, a complaint alleging the hauling of lumber on the claim and the erection of a rig by defendants for the purpose of boring for oil failed to show irreparable injury such as would justify the issuance of a temporary injunction, where it did not show that defendants were extracting, or threatening to extract, oil from the ground.

Martin v. Dunziger (California), 132 Pacific, 284. March 25, 1913.

MINER'S LIEN—ALASKA STATUTE CONSTRUED

Section 262, Civil Code of Alaska, giving a lien to persons performing labor on the construction, development, alteration, or repair of any building, flume, mine, tunnel, aqueduct, or other structure, limits the lien to work done in the development or improvement of a mine; and hence did not confer a lien for sluicing up the dump or for extracting gold therefrom, which was the ordinary work of a miner in the operation of a placer claim, having no relation to the development or improvement of the mine.

Noble v. Gustafson (Alaska), 204 Federal, 69. March 3, 1913.

COAL LEASE—CONSTRUCTION

Where the lessor of a coal mine, through mere oversight on the part of its employees and not from a consideration or interpretation of a mining lease, failed to demand an excess royalty to which it was entitled, this did not amount to a centemperate interpretation by the parties of a royalty clause in the lease. Such a clause will only be construed in light of the whole contract, and should be given such a construction as will not result in giving one party an unfair or unreasonable advantage over the other, though such construction violates the rules of punctuation and grammar.

Hillside Coal & Iron Co. v. Sterrick Creek Coal Co. (Pennsylvania), 86 Atlantic, 865. February 24, 1913.

MINING CO-TENANTS—ACCOUNTING

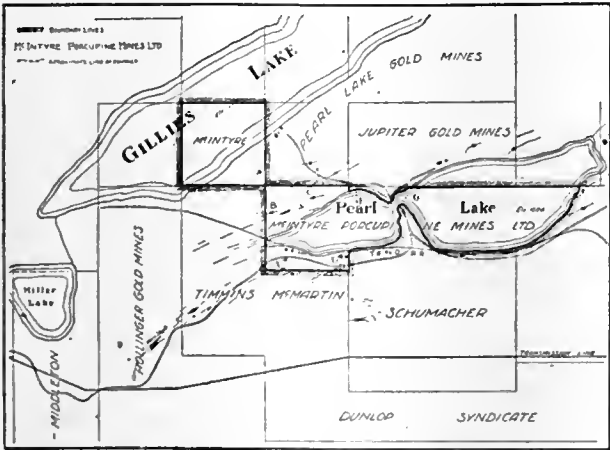

Two mining companies were equal owners and tenants in common of certain mining properties. One of them secretly worked the properties, extracted a large quantity of ore and appropriated the proceeds therefrom without accounting to its co-tenant. Subsequently it sold its interest to another company, part of the consideration being that the grantee should assume the debts and obligations of the grantor. In a suit by the defrauded co-tenant against the grantee for an accounting and damages, it was held (1) that the grantee could be sued directly for an accounting by reason of its outstanding contract to pay the grantor's obligations; (2) that the measure of damages should be the value of ore taken less the cost of mining the same. The usual rule fixing the gross value of the ore as the measure of damages against a trespasser who wilfully and unlawfully converts another's ore to his own use does not apply to co-tenants because the taking in the latter case is lawful, although it may have been done with bad intent. It is the refusal to account and divide the proceeds which gives rise to the cause of action.

Silver King C. M. Co. v. Silver King C. M. Co., 204 Federal (Utah), 166. April 5, 1913.

Company Reports

McINTYRE-PORCUPINE MINES, LTD.

This Company operates a gold mine at Porcupine, Ontario, and the report covers the work of the second year. The property covers about 148 acres, the largest portion of which is under Pearl and Gillies lakes. The available ore reserves are contained in not over 10 acres, which will supply enough ore for several years. The two largest veins discovered were cut by a diamond-drill under Pearl lake. The rocks outcropping on the McIntyre may be roughly

MAP OF M'INTYRE-PORCUPINE PROPERTY.

divided into three kinds: (1) a dark fine-grained basic-schistose rock which has been called 'basaltic' schist, and which, on close microscopic examination, appears to be an altered and recrystallized diabase; (2) a crystalline pearly-gray acid-schistose rock, showing distinct and plentiful quartz phenocrysts which has been called 'quartz porphyry'; and (3) a massive igneous rock which has been called a diabase, and which intrudes the basaltic schist on the north boundary either as a stock or laccolith. Broadly speaking, there are two bands of this basaltic schist enclosing a body of quartz porphyry; one band on the south and the other on the north of Pearl lake. The lake bottom itself is believed to be lying in the porphyry.

No. 1 and 4 shafts are down 300 ft. and levels have been driven at 100, 200, and 300 ft., and at 200 and 300 ft. respectively. Ore reserves opened are estimated at 129,478 tons, worth \$1,470,522, while probable reserves total 371,250 tons, worth \$3,408,750. A mill of 150-ton capacity is in operation, and duplication is now under way. A description will appear in another part of this journal. Mining and milling costs total \$4 per ton.

GOLDFIELD CONSOLIDATED REPORT

During the month of May, according to the report of Albert Burch, the general manager, the total production of the mine was 31,047 tons, of which the mining realization was \$43,767, and Milling & Transportation Co.'s profit and miscellaneous earnings were \$175,677. Operating costs per ton were as follows:

Mining, including stoping and development.....	\$3.31
Transportation	0.09
Milling	1.93
Marketing	0.05
General expense	0.25
Bullion tax	0.04
Construction	0.03
Marketing ore shipped	1.46
<hr/>	
Total costs	\$7.16
Miscellaneous earnings	0.02
<hr/>	
Net costs	\$7.14
<hr/>	
Development covered 3898 ft. While this work did not	

result in the discovery of any new orebody of sufficient importance to deserve mention, it did open for stoping several small shoots, as is evidenced by the fact that the value of the ore obtained from development was more than sufficient to pay for this work, including the cost of the usual large amount of work done in barren ground. On the second level of the Combination, the 136 BX sill was extended, and produced 180 tons of ore averaging \$12 per ton. The 414-D winze was sunk 86 ft. vertically below the bottom level preparatory to cross-cutting to the Reilly vein at that depth.

The No. 3 R sill on the new No. 1 level of the Mohawk mine was extended, and produced 189 tons of ore averaging \$16.50 per ton. On the old No. 1 level, about 600 ft. northwest of the shaft, the 170 BX sill was started and produced 244 tons of \$7 ore. The 345 A sill on the No. 3 level was extended, and produced 188 tons of ore averaging \$9 per ton. Driving was continued during the latter part of the month on the narrow streak of high-grade ore reported last month in the 293 D raise. It has improved in grade, but has not developed an important orebody as yet.

The 901 E sill on the intermediate of the Clermont-Jumbo below the No. 8 level, produced 432 tons of \$38 shipping ore.

COMPANIA MINERA CHONTALPAN Y ANEXAS

The property of this Company, which is situated in the Zacualpam district of the state of Mexico, has been operating almost continuously during the past year, according to the annual report which has just been issued. The Company has experienced some trouble with the Zapatistas, who have been in this district for some time, but the loss to this source up to date has been small, not exceeding \$4000, which damage was done to the assay office on one occasion. The concentration plant has been running without interruption for the past year. Plans have been made for the construction of a cyanide plant and the machinery has been ordered. It was expected to have this plant in operation by the first of the present year, but owing to the difficulties of transportation to the mines, due to disturbed conditions, this work has progressed slowly. It is expected, however, to have this plant in operation some time in July. The Company is capitalized at \$350,000 and its present position may be summarized as follows:

Development work, feet	2,910
Cost of development	\$ 41,589
Ore reserves, net value	420,900
Total production during the year.....	355,498
Expenditure in all departments.....	165,133
Profit	190,365

It was expected to begin the payments of dividends on March 15 of the current year of \$1 monthly. The condition of the business is reported to warrant larger dividends, but as the expenses of constructing the other new plant and other improvements have not as yet been paid, the larger dividends which are expected will be deferred until a later date, when the present obligations have been met.

BRISEIS TIN & GENERAL MINING COMPANY, LTD.

This Company operates tin mines at Derby, Dorset county, Tasmania, and gold properties in northeast Victoria, Australia, being worked by hydraulicking and dredging, respectively. During 1912, the tin properties yielded 539 tons of black tin, equal to 391 tons of metal, realizing an average of \$1033.44 per ton, a total of \$404,075. The dredges handled 1,547,600 cu. yd. of gravel averaging 11c. per yd., or \$170,230. Working costs were 5.5c. per yard. The total income was therefore \$574,305. The year's profit on all operations amounted to \$297,600, while \$216,000 was paid in dividends, and \$101,000 carried forward. The original Briseis property is nearly exhausted of tin 'drift,' and production will in future depend on the Krushka and Ringavoon sections, which will entail considerable engineering work. These sections are estimated to contain 800,000 and 8,947,300 cu. yd. of 'drift' respectively, containing 750 and 4569 tons of black tin, which should be won at a cost of \$908 per ton.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

MACHINE-DRILLS totaling 9018 are in commission in Rand mines.

BORAX, MAGNESITE, AND CHROME production of the United States in 1912 came solely from California, according to the State Mining Bureau.

BUILDING PERMITS issued in San Francisco between April 1906 and June 25, 1913, totaled \$50,000, involving an expenditure of \$225,227,000.

QUARTZITE PEBBLES suitable for tube-mills are being procured from the Powder river, Baker county, Oregon, for the Cornucopia Mines Company.

THE NEW 2-COMPARTMENT SHAFT of the Commonwealth Extension Mining Co., at Pearce, Arizona, was recently sunk 206 ft., and timbered 196 ft., in 30 days.

THE ARTHUR MILL of the Utah Copper Co. at Garfield originally contained 312 Nissen stamps. These were replaced by twenty-six 16 by 37½-in. Garfield rolls, and a similar number of 6-ft. Chilean mills. The capacity of the plant was increased from 3000 to 9000 tons per day.

FLUORSPAR PRODUCTION in the United States in 1912 amounted to 116,545 tons valued at \$769,163. This came from Illinois, Kentucky, Colorado, New Hampshire, and New Mexico, in the order named. Analyses of gravel fluorspar show 71.65 to 92.31% CaF_2 , 4.15 to 28.33% SiO_2 , 1.19 to 6.41% CaCO_3 , and 1.07 to 4.75% Fe_2O_3 .

COKE PRODUCTION of the United States in 1912 was 43,916,834 tons, valued at \$111,523,336, an increase of 8,365,345 tons, valued at \$27,392,487, over that of 1911. The output from by-product ovens is increasing, this being 3,200,000 tons, compared with the previous year. In all, there were 102,080 coke-ovens in operation. The average quantity of coke made from coal was 67 per cent.

MELANOCHALCITE is a copper oxide with SiO_2 , CO_2 , and H_2O . It is massive, occurring as a pitchy black layer a few millimetres in thickness over a nucleus of cuprite, this kernel being surrounded by a banded green zone of chrysocolla and malachite, and this again by quartz, the whole forming nodules having an average diameter of 120 mm. and of much beauty in cross-section. The black mineral when pure has a brilliant lustre and is very brittle. Hardness 4, and specific gravity 4.141. Analyses show the following composition: SiO_2 , 7.80; CO_2 , 7.17; CuO , 76.88; ZnO , 0.41; Fe_2O_3 , 0.07; and H_2O , 7.71.

BULLION ASSAYS are made at the Perth (Western Australia) mint in duplicate, one by weighing the cornets by a modification of Foord's compensating weight method, and the other by a direct-weight system. It has been found that under the conditions of work employed, there is the same difference in surcharge for equal differences in fineness, so that the surcharge of a cornet can be resolved into two parts: one a correction proportional to the fineness of the bullion, or proof, but constant for all fires, and the other a correction constant for all cornets in a fire, but varying in different fires. The first correction is made by adjustments applied to the weights and ordinary rider used, and the second by placing an extra 'surcharge' rider in the requisite position on the beam. The balance reading thus gives the fineness directly, corrected for surcharge.

GRAPHITE is useful in steam boilers to prevent formation of scale. The best and simplest way is to feed it into the feed-pump suction line. Feed about one pint (0.5 lb.) graphite into each boiler each day of 12 hours. For every 100 hp. above 250 hp. an extra one-third pint of graphite should be used. Boiler graphite forms a thin slippery film over the

boiler linings, protecting them from the action of acids in the water and associates itself with the sediment which is formed. This prevents the formation of hard scale and keeps the solid residue thrown down by the evaporation of the water in such a soft condition that it can easily be ejected from the boiler by the process of blowing off. If the water is not blown off sufficiently often, this sediment forms in quantities large enough to necessitate cleaning the boilers. Any boiler using bad water should be blown off every 12 hours. After all the old scale has been removed, the daily injection of graphite may be decreased slightly. It is the continual introduction of a small amount of graphite that brings about satisfactory results. In addition to the above, put about two quarts of graphite into a boiler each time after cleaning. The water will aid to distribute the graphite evenly over the heating surfaces. Boilers of more than 250-hp. capacity require an extra pint of graphite for each additional 100 horse-power.

AORICOLA, in 1556, wrote the following in 'De Re Metallica' regarding *venae profundae*, or fissure veins. The direction in which the 'head' (outcrop) of the vein comes into the light, or the direction toward which the 'tail' extends, is indicated by its foot-wall and hanging wall. The latter is said to hang, and the former to lie. The vein rests on the foot-wall, and the hanging wall overhangs it; thus, when we descend a shaft, the part to which we turn the face is the foot-wall and 'seat' of the vein, that to which we turn the back is the hanging wall. Also in another way, the 'head' accords with the foot-wall and the 'tail' with the hanging wall, for if the foot-wall is toward the south, the vein extends its 'head' into the light toward the south; and the hanging wall, because it is always opposite to the foot-wall, is then toward the north. Consequently, the vein extends its 'tail' toward the north if it is an inclined *vena profunda*. Similarly, we can determine with regard to east and west and the subordinate and their intermediate directions. A *vena profunda* which descends into the earth may be either vertical, inclined, or crooked; the foot-wall of an inclined vein is easily distinguished from the hanging wall, but is not so with a vertical vein; and again, the foot-wall of a 'crooked' vein is inverted and changed into the hanging wall, and contrariwise the hanging wall is twisted into the foot-wall, but very many of these crooked veins may be turned back to vertical or inclined ones.

A PECULIARITY common to all the mines in the Kolar goldfield, India, is the amount of mercury which is extracted during treatment by cyanide. It was a distinct trouble to the chemist in charge, according to H. M. Leslie, and entailed a great deal of extra work at clean-up. The amount of mercury which was extracted from the pans was considerable, as much as from ¾ to 1 oz. per ton being common. This mercury was deposited in the zinc-boxes, and materially and adversely influenced the quality of the bullion which was obtained. Its effect was to make the whole of the zinc exceedingly brittle, so that the contents of the first three or four compartments were amalgamated and formed a zinc sludge, the greater part of which was zinc. This had all to be removed at clean-up, together with a proportionately large amount of short zinc from the other compartments, in order to prevent a continual congestion of the boxes. The extraction of gold by cyanide was always satisfactory, notwithstanding the presence of the mercury in the material. The average original assay was from 2 to 3½ dwt. per ton, and the residue assayed from 8 to 21 gr. of gold per ton, as the weather and other conditions of treatment varied. A precaution which was found to be necessary in dealing with the 'leachings' from this class of material, was that the gold-bearing solution, before passing into the zinc-boxes, had to be freed of any slime which might have been drawn through the filter-cloths of the percolators. The most efficient type of settling-vat for this purpose was found to be one constructed after the pattern of a zinc-box, but of much greater depth, each compartment being packed with cocoanut fibre to which the fine particles adhered. These were cleaned out at intervals.

A New Mine-Rescue Telephone Equipment

The problem of devising ways and means for the protection of human life in mines is probably the most important question before mine-operators and the United States Bureau of Mines today. The laws of practically every state in which mining operations are carried on, call for regular inspections and also contain many safety regulations, not the least of which, in a number of states, is a section making compulsory the use of telephones underground.

During the past few years, the Western Electric Co. has furnished several thousand mine telephones for underground use. Through this intimate association with those interested in mine-safety work, attention was directed to the urgent need for some means of instant and continuous communication between an advance or rescue party equipped with its oxygen apparatus and the rear party outside the mine. In the past, members of rescue parties have lost their lives where loss of life could have been prevented by a quick and reliable means for summoning aid. The demand for this type of equipment has been met by the Western Electric Co., which has succeeded in producing a light, serviceable, and extremely simple telephone equipment for use in rescue work. In developing the apparatus, the United States Bureau of Mines was frequently consulted, in order that every requirement of this severe service might be fully covered.

A man wearing an oxygen helmet, which covers his mouth, cannot use the ordinary type of telephone transmitter, so that a special type of transmitter, known as the 'throat' transmitter, has been developed to meet this unusual condition. The transmitter is light and compact, and is provided with a soft rubber cup to adapt itself to the curves of the throat. This throat transmitter has been found by actual test to transmit speech practically as well as the standard Bell instruments. Both receiver and transmitter are held firmly in position in such a manner that they will not interfere with any type of oxygen apparatus now on the market. The telephone equipment used by the man on the outside is a standard switch-board operator's set consisting of a chest type transmitter and head-band receiver.

The rescue party is connected with the rear by means of a small wire cable consisting of two insulated copper conductors covered with a stout linen braid impregnated with moisture-resisting compound. This wire is in 500-ft. coils and is carried in a leather case fastened to the helmet man's belt, paying out as he advances. As the

coils are light, weighing less than 3 lb. apiece, several of them can easily be carried, and as one is run out, another can be connected by means of a plug and jack combination. The wire is so wound that it cannot become tangled and will pay out in whatever position the helmet man may have to assume. The total weight of telephone equipment carried by the helmet man, including one coil of wire, is a little over 5 lb. One end of the coil carries an aluminum-encased plug which connects with the head receiver and throat transmitter by means of an aluminum-encased jack. The other end is equipped with a similar jack connecting with a plug and cord running to a battery and apparatus box. This box is an essential part of the equipment and must be situated at the point from which the rescue party is being directed. It contains eight dry batteries mounted in a Patterson screw-type battery-holder, and a key, two jacks, and a battery gauge mounted in a removable compartment. The operator's telephone set is connected to the apparatus and battery box by means of a cord, plug, and jack.

In many cases it may be found desirable to use cable for carrying the talking circuit down a shaft or to the edge of the danger zone. For this purpose a large box, including a cable reel, is furnished. The box holds 1300 ft. of specially strong and flexible cable. A heavy ratchet and pawl are provided to prevent the reel from turning after enough cable has been paid out. Connections with the apparatus box and the coil carried by the helmet-man are effected by means of aluminum-encased jacks and plugs, while electrical contact with the inside end of the reeled cable is made through collector rings and commutator brushes connected to a jack.

The entire outfit has been designed and constructed with a view to providing practical and serviceable telephone equipment for mine-rescue work. Service tests have proved that this object has been attained, and the telephone equipment should be of incalculable benefit to those engaged in rescue work.

The Haldane Flame-Test Apparatus

While the percentage of fire damp in mine-air can be readily estimated by means of the cap on a lamp-flame, no equally simple test has hitherto been available for estimating the amount of black-damp in the air. Black-damp, as ordinarily met with, is simply nitrogen mixed with from about 5 to 20% of carbon dioxide. It is the residual gas resulting from various oxidation processes in mines and the surrounding strata. It might, perhaps, seem simpler and more logical to discard the use of the term 'black-damp' and refer only to the deficiency of oxygen and excess of carbon dioxide in the air. To the miner, however, black-damp is a real entity; and although the proportion of carbon dioxide in black-damp varies, black-damp is quite definitely characterized by its origin and by its effects on lights and on men. When air is mixed with black-damp, the oxygen percentage of the air is lowered in proportion to the amount of black-damp added. The percentage diminution in the oxygen is thus a measure of the percentage of black-damp, unless fire-damp or some other gas is present in appreciable amount, and helps to lower the oxygen. A flame-test can thus be graduated either to percentages of oxygen, or, as seems simpler, to percentages of black-damp. As the oxygen percentage in air diminishes, the flame of a candle or lamp is affected in two ways. In the first place, the light given steadily diminishes. Roughly speaking, the light of a candle or lamp diminishes by 30% with a fall of 1% in the oxygen percentage, and the flame will no longer burn when the oxygen has fallen from the normal (20.93%) to about 17.5%. A further effect is that the flame becomes less and less stable as the oxygen percentage diminishes; it is more and more easily blown out by any chance draught or movement. To those who work or move about in 'dull' air, this is painfully familiar: their light is constantly going out. It is upon this latter fact that the test now to be described is based.

The apparatus for the test consists of a piece of glass tube and some thin tapers. When a lighted taper is held inside the tube, an upward draught is, of course, produced by the heat; and this draught varies in strength, according as the taper is held high up or low down in the tube. The draught tends, naturally, to blow the flame out; and, according to the percentage of oxygen in the air, the flame is extinguished at a point lower down or higher up in the tube. The size of tube chosen as being convenient for the test is one 7 in. long by 0.75 in. internal diameter. The main graduations are in percentages of black-damp, from 0 up to 10½; and there are subsidiary corresponding graduations in percentages of oxygen, from the normal of 20.9 down to 18.8. Below about this percentage the taper will no longer burn in the tube; and when held upright, it will no longer burn outside the tube with less than about 18.2% of oxygen or 13% of black-damp; but, when held in a horizontal position, it will still burn until the percentage of oxygen has fallen to about 17.2, or 18% of black-damp. There is thus a wide range within which the proportion of black-damp can be estimated by the taper and tube. As the flame becomes very small when it is just on the point of extinction, its position with respect to the graduations on the tube can be determined quite easily. The lighted taper should be first pushed up to a point where it burns easily, and then gradually lowered. With a little practice, it is easy to find with considerable exactness the point at which it just extinguishes. If there is much black-damp in the air, it may be necessary to push the taper through the tube before lighting it, and then to lower it cautiously into the tube. The tapers used are 1/16-in. diameter, the thinnest that it was possible to obtain. Thicker tapers are much less convenient, and are apt to crack the glass. The tubes must, of course, be held vertically while the test is being made and to prevent the glass from cracking. The tube of the size specified has been graduated by experiments in an air-tight chamber, the black-damp being produced either by respiration or by allowing gas to burn in the chamber. The experiments showed that the tube indicates the state of the air with surprising sharpness and accuracy. Experiments show that, under favorable conditions, the accuracy is greater than that ordinarily reached by a Hempel gas-analysis apparatus. Similar accuracy cannot, however, be expected in tests made underground, unless troublesome corrections are introduced for the varying percentage of moisture in the air and the varying proportion of carbon dioxide in the black-damp, and unless great care is taken as to the exact point at which the flame is just extinguished.

It appears from these experiments that the method is sufficiently delicate to make it very useful in estimating the percentage of oxygen, or of black-damp, in the air of a mine. For ordinary practical purposes, it is greatly preferable to chemical analysis, as it gives the information at once, and the test can be repeated in as many places as may seem desirable. It does for black-damp what the cap-indications do for fire-damp, and with its help the proper distribution of air in a naked-light mine can readily be controlled. For instance, the return-airways may be tested at different points, and excessive leakage, or defective arrangement of regulators, can be detected at once. The tube method must not, however, be supposed to do more than it actually accomplishes. For instance, it does not, of course, detect carbon monoxide. Air containing after-damp, or fumes from explosives or an underground fire, might be excessively dangerous, although the tube test would show that the air contained less than 8% of black-damp. Unless the tube gave practically no indications at all of impurity, one could not be sure from its readings alone that dangerous proportions of carbon monoxide were absent from the air of a mine. Of course, the tube would be far better than a lamp. Arrangements have been made with Siebe, Gorman & Co., Ltd., H. N. Elmer, Agent, 1140 Monadnock block, Chicago, to supply the whole apparatus complete, with metal case and an inner tube to hold the tapers, and a holder for use when a taper has to be held far up in the tube.

EDITORIAL

A GERMAN professor with a new divining rod has arrived in this country on the same steamer with a scientist who has a light that duplicates daylight. We second the suggestion of the New York Sun that they get together and hunt turtles for the Friedmann Institute.

NOME citizens are reported to have held a mass-meeting to protest against the new mining law passed by the territorial legislature and to appeal to Congress for its revision; rather a sorry comment on the vociferous demand for home rule that has been coming from Alaska.

REPORTS from Antwerp state that the control of the Trinidad Oilfields, Ltd., has passed to the Royal Dutch-Shell company, unusual interest being lent to the transaction by the statement that the purchase was made jointly with the British Western Isles, Ltd., a Rothschild company. The co-operation of two such large interests in the Trinidad fields is strong evidence of their great probable value.

HAVING two trains pass on the same track has been frequently, if inadvertently, tried, but the experiment has been wholly without success. At the Rosas mine in Sardinia, Mr. E. Praetorius has found how to make two buckets on an aerial tram pass on the same rope; and as usual, it is simple when you know how. This ingenious piece of engineering is described and pictured in the June number of our London contemporary, *The Mining Magazine*.

SHIPMENT of an initial consignment of East Texas brown iron ores from Galveston to Philadelphia has been made as part of a contract to supply 300 tons per day. The outcome of the venture will be a matter of interest to the West generally. The brown ores of Texas, while low in phosphorus, are also rather low in iron, and shipments on a large scale can scarcely be expected to maintain a grade of over 32 to 35 per cent. Freight rates to the ore fields are heavy, and there seems to be a better opportunity for the development of iron smelting within Texas. There is a fair market for pig iron in that state, and a larger market for such steel products as cotton ties and fence wire, while the demand is brisk for the ammonium sulphate that is a by-product of coke-making. Plans are well advanced for the beginning of smelting in Texas, and it is to be hoped that iron-making may take its way westward in company with 'the star of empire.'

POISONING from an unusual cause is reported by Dr. Louis Casamajor in a recent number of the *Journal of the American Medical Association*. The men affected worked in the mill of a large mine, of which zinc was the chief product, and after periods of from six months to three years developed a pathological condition of the central nervous system, affecting principally the mechanism of walking and equilibrium. The ore was practically free from lead and arsenic, but contained quantities of manganese, to which Dr. Casamajor is inclined to attribute the effect produced. At the risk of seeming to treat a serious subject with undue levity, we venture to suggest that a similar effect is exhibited within a shorter period following the ingestion of *spiritus frumenti*.

SUGGESTIONS for a scientific non-partisan tariff commission are met regularly at Washington by the statement that the members of Congress concerned in the revision, themselves constitute a commission directly chosen for the task in hand. An excellent side-light on their competence is thrown by the testimony of Mr. A. B. Fall, senator from New Mexico, to the effect that there is a 'zinc trust' and that it controls most of the zinc deposits and smelters of this country. In fact, the most important sources of zinc ores in the United States are the Joplin, Leadville, and Wisconsin districts, and no company controls any one of these. The most important use of spelter is for galvanizing, and probably the largest user is the United States Steel Corporation, which controls the Edgar Zinc Company, which, however, operates less than 10 per cent of the retorts in this country. The New Jersey Zinc Company is the largest single concern and does dominate the zinc oxide business. In the mining of ore, however, or the making of spelter it plays only a minor part. The zinc business is particularly free from control, and it is a pity that matters so important as the tariff should be decided by those who are so ignorant.

JULY brings dog days (elsewhere than in California) and also dividend disbursements. According to the computations of the leading financial journals, over \$266,000,000 in dividends and interest on railroad and industrial securities was paid on July 1. This represents an increase of \$12,000,000 over July 1, 1912. But what is more encouraging is the decrease in new securities issued. Railroads have placed \$152,000,000 less of new securities in the first half of this year than they did in the corresponding period of 1912, while industrial corporations have issued \$227,000,000 less. This shortening of sale is most encouraging for the country at large, but leads to dull times in Wall Street. It is related that the junior partner of a firm of brokers that formerly did a large business was recently observed leisurely taking a hearty lunch. To the question as to how he could afford to remain away from his office for so long a time, he replied, "Our customer is sick." Preparations to finance the moving of crops next fall are already under way, and call money in New York during June commanded 2.291 per cent, or over 3½ per cent less than well

secured time loans, an unusually large margin, and one that should result in a good supply of ready money in the autumn.

CONDITIONS in Mexico appear to be growing steadily worse regardless of the efforts which the present administration has made to stem the tide of revolution and brigandage which has swept the country from the Rio Grande to Guatemala. The latest reports from Mexico state that the Huerta government is bankrupt and on the verge of collapse; Felix Diaz, the instigator of the revolution which resulted in the overthrow of the Madera regime, and who has been generally accepted as the next president, has sailed for Europe; President Huerta is anxious to be relieved of the presidency; and Francisco de la Barra, Mexico's foremost diplomat, who will be remembered as the representative of Porfirio Diaz at Washington and who succeeded him as president, has resigned as Minister of Foreign Affairs. So it would appear evident that the present administration is facing a more serious situation at the present than at any time since taking up the reins of government. With the revolution gaining ground and the apparent inability of the federal troops to cope with it, a lack of funds and an ever changing personnel of the government officials, it would seem that there is no hope within Mexico for her salvation. However, to those who have tried and are trying to keep the mines and mills going in spite of the many handicaps and discouragements, while there is apparently no immediate solution, it is a long road that has no turning, and it is to be hoped that the pendulum will soon swing in the opposite direction.

ELSEWHERE in this issue, Mr. Herbert Lang discusses the conditions governing the combustion of liquid fuel. An atomized liquid, which superficially resembles a gas, differs essentially from a true gas, and even more markedly from a solid combustible, in its method of burning. In the case of a gas, it is easily seen that proper care must be taken to secure its thorough mixing with a sufficient quantity of air in order to provide the oxygen necessary for the heat-liberating reaction, avoiding any undue excess, since air consists largely of nitrogen, which carries away heat without having been productive of any. In the case of solid fuel, this almost adjusts itself in any reasonably well designed furnace, since the fuel and air move in contrary directions, the fuel burning away as fast as air is supplied for the purpose. In an oil-fired furnace the fuel and air move in the same direction at nearly equal speed, cross-currents providing for the proper mixing. Careful regulation is necessary to constantly maintain the proper proportion of air and liquid. In addition, the minimum temperature of combustion must be maintained as well. A hot coal will continue to burn, though in contact with a cold surface, if supplied with air for combustion, because the coal keeps itself hot enough by the heat it liberates. A gas-air mixture, or an air-liquid mixture, will not continue to burn under such circumstances, because it radiates heat so rapidly that

it quickly cools itself below the minimum combustion temperature. The solid fuel burns on its grate and radiates its heat to nearby objects; a gas or liquid burns throughout the combustion space, and, if allowed to radiate its heat too quickly, soon cools below the temperature of combustion. Hence it follows that the proper mechanical construction of a firebox or furnace for burning liquids differs markedly from that which gives the most satisfactory results with solid fuel.

FURTHER details are now available concerning the huge metallurgical plant to be erected to treat copper ore by leaching at Chuquiamata, as discussed at some length in our editorial columns of June 21. The ore, which is mined by steam-shovels, will be subjected to a preliminary crushing in gyratories, crushers, and rolls, and then distributed, by a system of belts, into concrete vats, lined with acid-proof materials and holding 9000 tons each. It is estimated that one day will suffice for filling a vat, two to three days for acid treatment, and washing, and one day for discharging, each vat holding one day's ore supply. The extraction process might perhaps be more accurately termed soaking, rather than leaching, since it is not necessary to cause the solvent to percolate through the ore to the same degree as is required in cyaniding gold ores. The pregnant solution will be drawn off into solution tanks, preliminary to electrical precipitation. The leached residue will be excavated from the vats by clam-shell buckets operated from a traveling bridge, somewhat resembling the system used in reloading coal from stockpiles, and the residue will be piled upon the waste dump by a series of belt conveyors. The plant is to be built upon a side-hill having a 6° slope and of sufficient extent to provide ample storage room for the great quantity of tailing which will in time be produced. The contract for the construction of the electrical power-plant and transmission line has already been let to the lowest bidder, a German firm, for approximately \$3,000,000; the equipment including a 40,000-kilowatt, oil-fired power-plant on the seacoast, a 100-mile transmission line to the mines, and the necessary auxiliary sub-stations and transformers. It is hoped to have the plant in full operation within three years, but construction work on so large a scale at so great a distance from headquarters may easily involve unexpected delays.

Law and Mining in West Virginia

We have so far refrained from comment on the coal-mining situation in West Virginia, for much the same reason that an onlooker might well hesitate to assess the blame in the progress of a Donnybrook fair. We can, however, agree heartily with Mr. Theodore Roosevelt in putting the blame squarely up to the courts for the part they have played in a situation which in no phase evokes admiration. On the one hand, it has been charged that armed attacks upon labor camps were made by men who were presumably agents of the operators, that the declaring of martial law was unjustified, and "the employing operators have not only discriminated

in utterly unjust and anti-social fashion against labor unions, but have endeavored to keep the miners in a state of practical serfage by the use of company stores." On the other hand, it is alleged that demoralization of the profitable mining industry of West Virginia was incited by operators in other districts, who found a ready tool in labor leaders anxious to reap personal profit through stirring up trouble. Of the measure of truth in these counter allegations we profess no special knowledge. But it must be evident to any sober thinker that the courts of West Virginia, in declaring unconstitutional all the legislative measures intended to prevent the exploitation of employees through the aid of the company store and, on the other hand, in refusing to permit that degree of combination among operators which would preserve them from cut-throat competition, is in large degree to blame for a condition which is almost synonymous with anarchy. It is truly remarkable that the courts, supposed to be the guardians of the rights of the people, have developed into institutions of slow-witted legalism which seem to be chiefly effective in obstructing the securing of the rights of labor and capital alike. That anarchy which is misnamed socialism by such organizations as the Industrial Workers of the World finds its chief justification in the manner in which the courts defeat the will of the people in attempting to adjust themselves to the ever-changing conditions of that social organism which we call the American nation. Cannot some effective means be devised to convey to the legal mind the fact that we are now living in the twentieth century?

Geology of Kalgoorlie

Kalgoorlie is one of the world's great goldfields, and to engineers it is of wide interest, not alone because of the production, notable as that is, but because of the occurrence of the ore, the presence of tellurides, and the marked advances that have been made in mining and metallurgy in the field. A detailed study of the mode of occurrence of the ore is well worth while. We are glad, therefore, to print this week the first of a series of articles written by Mr. Malcolm MacLaren, and describing the geology. The articles are taken by permission from an unpublished report upon the field made for three of the leading companies. They cover the main part in its scientific phases, except a most interesting chapter on petrology more appropriate for publication elsewhere. The parts of the report dealing specifically with the ore deposits, being the private property of the companies, cannot be printed at this time, but in the material now so generously made public, enough is given to enable the trained student of ore deposits to recognize the essential steps in the deposition of the ore. Those not already familiar with the district should read in this connection the admirable account of the ore deposits prepared by Mr. C. O. G. Larcombe, and forming volume V of the *Proceedings* of the Australian Institute of Mining Engineers. While the nomenclature of the rocks differs in the two reports, in which particular they run true to form for geological reports on the pre-

Cambrian, the general sequence is the same.

Except the quartz veins, here of minor import, and the alluvial deposits, which are aside from the general discussion, the ore occurs at Kalgoorlie in two forms: The first is the wonderful Oroya Brownhill 'pipe', a great body of ore outcropping in Brownhill ground and dipping through the Brownhill Extended, Associated Northern, and Oroya. It is found in what Mr. Maclaren calls the 'Older Greenstone' near the contact of the latter with his 'quartz-dolerite'. For these rocks Mr. Larcombe uses the terms 'metamorphic tuff' and 'quartz-andesite', respectively. This orebody was formed by replacement in a position determined by intersecting fault planes. The bulk of the orebodies, however, occur in the quartz-dolerite (or quartz-andesite) along fissures or 'shear zones.' In this they resemble the veins at Cripple Creek. These fissures are only significant and only contain valuable orebodies when in the quartz-dolerite; presumably because it was the only rock that was sufficiently brittle to break in long fissures, thereby forming what Mr. C. R. Van Hise has called 'trunk channels' for underground circulation. Both Mr. Larcombe and Mr. Maclaren agree as to the ores being primary and intimately related to the quartz-dolerite. Mr. Larcombe sees no reason why the ore-shoots should not continue indefinitely in depth. Mr. Maclaren says that the value of a given lease is conditioned by the extent to which it covers the quartz-dolerite; plainly indicating a belief that the veins will be found of no value where they pass outside this especial rock. It is perhaps unfair to speculate more closely as to what Mr. Maclaren does or does not believe about the genesis and structural features of these ores, since the time is not ripe for full exposition of his views. That they are well founded will be certain to everyone who reads the part of the report now made public.

It remains but to express here appreciation of the far sightedness of Mr. H. C. Hoover, who projected the work, and the liberality and broad-mindedness of Messrs. Bewick, Moreing & Co., who, charged with the management of the companies concerned, saw the value in and supported the making of a geological survey of the district as complete and as scientific as any conducted elsewhere at government expense. Science has no enemy save the ignorant, and the miner has no such helper as science. It is a pleasure to print in a mining journal a scientific report made by a distinguished geologist for a firm of engineers managing a group of mines of first magnitude.

The Rand Strike

Not since the days of the Jameson raid and the war of 1898 has Johannesburg been the scene of as much turmoil as has recently been experienced in that city as a result of the strike of the Rand miners. At the New Kleinfontein a dispute over working hours led to a strike, which was settled by the management granting the requests of the men. The next demand was for the dismissal of those strike-breakers who refused to join the union. The management was obdurate and the workmen

of mine after mine struck in sympathy with the New Kleinfontein men, the strike even spreading to the coal mines, and the railway employees threatened to go out. Only the presence of troops maintained electric-power service. After several days of rioting, in which over a hundred lives were sacrificed in addition to property being damaged and the losses due to the closing of the mines, a settlement of the difficulties was reached by a committee appointed by the Government and a committee of the strikers. The terms of settlement were that the strike should be declared off; the New Kleinfontein strikers are to be reinstated, and the Government is to grant suitable compensation to the strike-breakers, who are in no way to be victimized; the strikers in other mines are to return to their work and are to be taken back as mining operations are resumed; representatives of the workers are at liberty to lay any other grievances before the Government, which will inquire into them. While the strike is regarded by the miners as a victory for organized labor, are the terms of settlement commensurate with the loss of life and property which has been occasioned, and could not the same results have been accomplished by more peaceful means? Like the disarmament of the nations and the much-talked-of universal peace, it seems to be a matter of theory rather than of practice, but it is to be hoped that by a closer relation and a better understanding between employer and employee, such catastrophes as the present one may be avoided and the questions in dispute decided by arbitration, which is always the ultimate result, regardless of how much blood has been shed previous to the settlement.

While most of the strikers have returned to work, the peace terms have not been generally accepted. Six thousand native black laborers from three of the large gold mines have refused to go into the mines unless granted an increase in wages, and a thousand in another property are reported to have broken out of their compound and were only made to return when forced to by the troops. Should this attitude of the native labor spread to the other 250,000, which are employed in the district, the result might be disastrous.

The Government has recently ordered a cessation of recruiting native laborers in the district north of 22° south latitude, which will eventually cause the mines to lose 25,000 native laborers, and this fact has accentuated the difficulties experienced in handling the white workmen. Not a few observers consider that the gold production on the Rand has already reached its zenith, and if to the increasing operating costs and a decreasing return per ton milled are to be added the heavy burdens resulting from the exactions of labor unions, the repaid decline of the gold-mining industry on the Rand is not far in the future. The present outbreak must seem peculiarly ungrateful to Mr. R. W. Schumacher, of the Rand Mines, and the Central Mining & Investment Corporation, Ltd., who has been especially active in securing for miners the opportunity to purchase homes on the easiest possible terms and also in securing them more favorable terms for contract work.

Geology of the Kalgoorlie Goldfield—I

By MALCOLM MACLAREN and J. ALLAN THOMSON

The geological and other data contained in the following pages form a portion of the results of a geological survey of the Kalgoorlie goldfield in Western Australia, extending from April 1909 to March 1910. The initiation of the survey is to be ascribed to H. C. Hoover, whose knowledge of the field had indicated the probable utility of a close geological examination. It was at first hoped that the leading companies of Kalgoorlie and perhaps the

Australian border, the surface then sinking to the Central Australian depression. Its northward extension is somewhat indefinite, but it passes at least beyond the Pilbara goldfields. In the immediate neighborhood of Kalgoorlie the average height of the plateau above sea-level is some 1250 ft., while the maximum height is reached at Mt. Burges (1922 ft.), nine miles north Coolgardie. No figures are available for the majority of the lake-beds, but that of Hannan's lake, 1060 ft. above sea-level, may be assumed to represent the average level of these. The physiographical feature of the region is thus its low relief, Mt. Burges, Mt. Robinson, Mt. Hunt, Mt. Monger, and others, being merely semi-isolated mounds or the higher portion of short ridges, in a gently undulating plain.

Physiographical Features

In a region of long-continued erosion, physiographical features become inevitably the expression of the geological structure, and here is no exception to the general rule. The ridges are generally the harder greenstones, though at Kanowna, quartz-porphry, and at Kurrawang, coarse conglomerate rise to ridges. The valleys and lower land generally is occupied by sedimentary rocks or by porphyrite, which decomposes just as readily and to a very similar product. The general aspect of the region is one of broad shallow valleys with low comparatively narrow ridges. To the south of Coolgardie as far as the Londonderry, in the contact-metamorphosed amphibolite, ridges and valleys are narrower and the surface assumes a comparatively rugged character. On the whole, the general trend of the ridges is north-northwest with the strike of the rocks, but low watersheds trending east-west have been occasionally developed, as between Coolgardie and Kalgoorlie, by the ancient drainage system of the area.

The mines of Kalgoorlie itself are disposed along a low ridge some five and one-half miles in length, of which, however, only the southern portion has been as yet highly productive. This is 'The Mile' of the inhabitants and 'The Golden Mile' of journalists and company promoters. The ridge strikes with the foliation of the country north-northwest and south-southeast, and is flanked on either side by a broad shallow valley. Its average height is only 100 ft. above that of the valley bottoms. Its highest point is Mt. Charlotte (1378 ft.), which has been utilized as the site of the reservoir from whence the water brought from the Darling ranges, near the coast, is distributed. The lowest point in the immediate neighborhood is, as already mentioned, the bed of Hannan's lake (1060 ft.), some two and one-half miles south of the principal mines. The total difference in level is therefore only 320 ft., and the most striking features in the Kalgoorlie landscape are indeed not natural, but are the great tailing dumps of the various mines. The valleys of the region occupy the lines of an ancient drainage system, now largely

WESTERN AUSTRALIA.

Government of Western Australia would unite in sharing the cost of the survey. Finally, however, it was borne by the Ivanhoe Gold Corporation, Ltd., the Oroya Brownhill Co., the Lake View Consols Co., and in a certain sense by the authors. The burden of the work fell on the senior author. The petrologic work was largely left in the hands of the junior author, who also was responsible for much of the mapping of the northern end of the Kalgoorlie auriferous area.

Situation and Topography

The Kalgoorlie goldfield lies on the great inland plateau of Western Anstralia. The western boundary of this plateau is the sharply defined fault escarpment lying parallel to and only a few miles from the coast at Perth. Its main southern boundary is apparently the fault line that forms for so great a distance the shore of the great Australian Bight. To the east the plateau probably reaches to the South

filled and buried by wind-driven sand and débris. They contain no defined watercourses or thalwegs.

History of the Kalgoorlie Goldfield

The discovery of gold at Kalgoorlie may be regarded as an indirect result of the impetus given to prospecting in Western Australia by the finding of gold at Kimberley in 1886, and at Yilgarn (Southern Cross) a year later. Western Australia had previously been considered a country barren in gold, an illusion shaken by these discoveries and completely shattered by later reports, in rapid succession, of gold from the Pilbara, Ashburton, and Murchison. Finds so widespread and so rich as some of these were, naturally attracted the attention of the vagrant prospectors of the eastern states, who searching for new fields, soon arrived in the colony, and pushing beyond the outposts of civilization, spread eastward with horses and camels into the dry and poorly watered inland plains. Previously the country had been known only to explorers, of whom the principal were Lefroy (1863), Hunt (1864), Forrest (1871), Giles (1875), and Lindsay (1891). Their attention was directed rather to the pastoral than to the mineral resources of the country. Hunt, in particular, with a large wagon train, had discovered and occupied the areas now held by the Hampton Plains Co. in the vicinity of the goldfields. His object was solely the acquisition of pastoral lands; to this end he selected the valleys and carefully avoided the poorer stony ridges on which Coolgardie and Kalgoorlie are situated. By so little, in view of the immense area taken up, was fortune missed.

Hunt spent some time in the country digging wells and tanks to fit the areas selected for occupation by cattle, and had had more opportunity than other explorers for examination of the rocks. He noted numerous quartz outcrops, and it was perhaps the rumor of these that determined several prospectors to examine the country lying east of Southern Cross. Favored with good rains, two, Bayley and Ford, pushed eastward in June 1892, across the great granite belt, following the track of Hunt's wagon wheels, not wholly obliterated after 28 years of desert dust and storm. They rested at the Gnarlbine 'soak,' and then moved northeast to a 'gnamma' hole, known to the aborigines as Gulgurda, afterward to be softened by the digger to Coolgardie. Camping on what is now known as Fly Flat, they soon detected gold lying on the surface, Ford picking up a slug weighing half an ounce.

Alluvial Gold

Western Australia is one of the few auriferous areas in the world in which direct support is given to the vulgar belief that gold nuggets lie on the surface for the picking up. After rains and before the winds have had time to obscure the washed surface with the light desert dust, grains and nuggets of gold are readily seen by the trained eye, a method of search known as 'specking.' Three or four weeks dry-blowing and specking had yielded to Ford and Bayley 200 oz. of gold, when they were forced to return to Southern Cross to replenish their supply of provisions. With the digger, shallow alluvial gold is merely the promise of great stores of vein gold,

and the two prospectors on their return lost no time in examining the adjacent quartz outcrops. They were more fortunate than the majority of prospectors who have acted on this assumption, for a short search disclosed the cap of a rich gold-quartz vein, from which they had by the end of the day and with the aid of a hatchet and pestle and mortar obtained more than 500 oz. of gold. They had allowed no inkling of their first discovery to escape, and it was not until the application for a reward claim was safely lodged, on September 17, 1892, with the warden at Southern Cross that the news of the great value of the discovery and of its locality was made public.

A steady inrush to the new Eldorado naturally took place, but its magnitude was at first limited by the difficulty of transport, by the high cost of provisions, and most of all, by the great scarcity of fresh water. When all available auriferous ground had been taken up at Coolgardie, prospectors spread out from that centre scouring the country for many miles in search of new fields. When the discovery was reported, a wild scramble took place to peg out in the neighborhood of the original reward claim. In these 'rushes' every available means of transport was pressed into service, camels, horses, bicycles, carts, and even wheelbarrows being mingled with the throng that pressed forward on foot and carried their supplies on their backs. Most ended in disappointment, one or two in disaster. Kalgoorlie was discovered in 1893 and Londonderry, Black Flag, Kanowna (White Feather), and Bulong (I. O. U.) in 1894. By the end of 1895 more than 10,000 people were collected in the various camps.

Gold Discovery at Kalgoorlie

Gold was discovered at Kalgoorlie on Saturday, June 17, 1893. The finders were Patrick Hannan, Thomas Flannagan, and Dan Shea, who were on their way from Coolgardie in response to a nebulous rumor of rich gold at Mt. Yule (perhaps Mt. Jewel, northwest of Kurnalpi). It proved an *ignis fatuus* in the end, and the three had camped for the night on the western side of a ridge 22 miles east-northeast of Coolgardie, near the site of the present Hannan street railway station. The first-named seized the opportunity afforded by the halt to search for gold in the neighborhood of the camp and soon discovered ('specked' in local parlance) gold lying in small nuggets on the surface. All thought of the district of Mt. Yule was abandoned, and Hannan hastily returned to Coolgardie to secure a 'reward' claim. The following day, Sunday, June 18, the whole available population flocked to the new Eldorado of 'Hannan's Patch,' as it was then called. The so-called 'alluvial' ground west and southwest of Cassidy hill and Maritana hill (Mt. Gledden) proved very rich for a time, and occasional large nuggets were obtained, none, however, weighing more than 24 oz. These are, of course, small in comparison with the famous nuggets of Victoria and New South Wales, but the climatic conditions obtaining in the interior of Western Australia preclude the accretion of gold necessary for the growth on a large scale of alluvial gold. Other 'dry-blowing' areas

were soon discovered, the principal being in the neighborhood of Slug hill to the south of the present Boulder mines. So-called 'deep-leads' were also found both east and west of the main ridge, but the yield of surface gold was never important.

Lode Mining

The lack of alluvial gold turned the attention of the diggers toward the possibility of discovering the lodes from which the surface gold was assumed to have been derived, and claims were pegged out in all directions, but mainly north and south along the Kalgoorlie ridge. Most of the miners on the new field had gained their experience in Victoria, New South Wales, Queensland, and New Zealand; it was therefore natural that the search for vein gold should be confined to quartz outcroppings. These had furnished the gold of the neighboring Coolgardie field and there was nothing to indicate that different conditions obtained at Kalgoorlie. It thus happened that the rich mines of the Boulder belt, two miles south of the original discovery, were pegged out on account of their worthless quartz veins. Capital from Adelaide and Melbourne was furnished to open up most of these mines, but development was for a long time exceedingly slow. It was known even then that the rich deposits of the outcrops of the majority of Western Australian lodes did not persist below the zone of oxidation; it was therefore feared that Kalgoorlie lodes would form no exception to the general rule and there was, from market considerations, a rooted disinclination to pass into the sulphide zone lying at an average depth of 180 ft. beneath the surface. The Great Boulder mine led the way into this zone, and its success encouraged others to follow.

The first real hope for the permanence of the field was, however, engendered by the discovery of tellurides of gold. An event of such importance warrants some description in detail, the more so as after the lapse of only 14 years there is now a conflict of opinion not only regarding the events that led up to the discovery, but even with regard to the identity of the discoverers. With some trouble the following sequence has been pieced together.

The First Tellurides

The scene of the discovery was the Block 45 mine, now included in the ground of the Oroya Links, Ltd. The then manager, Richard Eades, had obtained rich assays from samples that showed little or no free gold. Repeated tests had proved that the gold was associated with or contained in a soft pale bronze mineral, and samples were therefore sent both to Kalgoorlie and to Coolgardie assayers. Eades indicated the mineral carrying the gold and asked for a determination of its nature. The assayers tentatively suggested one of the iron sulphides, but the extreme softness of the unknown mineral at once showed that this suggestion was incorrect. On Sunday, May 24, 1896, specimens were taken by Robert Gibson from the Block 45 mine to his 'camp' on Maritana hill and were there shown to Allen Davidson and Erle Huntley as typical of the rich 'sulphides' of the mine. The last-named had had some

experience of telluride ores at the Mt. Shamrock mine in the Mt. Burnett district, Queensland, where gold is associated with hessite (silver-gold telluride), tetradyomite (bismuth telluride), and frenzelite (bismuth selenide), and he suggested that the new mineral was a telluride of gold. This mineral was unknown to the others present and its very existence was indeed scouted, but the question was soon settled by a reference to a 'Dana' lying handy. Huntley tooled away fragments of the mineral and on the following day made blowpipe tests on them, confirming the accuracy of his suggestion. That evening, in the course of conversation, he communicated the news of his discovery to Peter MacIntyre, then representing the company holding the rights to the cyanide patents in Australia.

Definite Proof of Discovery

On Wednesday, May 27, 1896, Eades forwarded two samples to A. G. Holroyd, of Holroyd & Tinley. These, on assay, yielded respectively 31 oz. 10 dwt. and 92 oz. 7 dwt. gold per ton. Following his usual custom, Holroyd 'panned off' some of the ore and was immediately struck by the discrepancy between the high assay value of the original samples and the meagre quantity of free gold in the pan. The first sample indeed showed none, while the second gave only 2 oz. 7 dwt. per ton of ore. The concentrate obviously contained nearly all the gold. As in most new mining camps, there was then a considerable interchange of ideas among members of the same profession at Kalgoorlie, and Holroyd showed samples of the ore and of the concentrate therefrom to Peter MacIntyre, who informed Holroyd that Huntley's tests already made had indicated telluride of gold. Tellurides of gold were then almost unknown minerals, although the great richness of the Cripple Creek mines in Colorado had impressed their importance on the mining world, and there was naturally some haziness concerning the nature of the tests for them. MacIntyre therefore lent 'Fresenius' to Holroyd and shared in the tests. The existence of telluride of gold was soon proved by blowpipe and wet tests. On Friday, May 29, Holroyd communicated the news of the discovery to the press, probably to the *Coolgardie Miner*, for the first reference to the matter in the *Kalgoorlie Miner* is in the issue of June 1, where also it is stated that the priority of discovery was claimed by Mr. Hunter. Meanwhile Erle Huntley and A. J. McGeorge had been making further investigations and on June 2 they published the first complete analysis of a Kalgoorlie telluride of gold: gold, 42.6; tellurium, 54.1; silver, 0.7; iron, 0.9; arsenic, 1.1; sulphur, 0.4; total, 99.8. The iron, arsenic, and sulphur were obviously due to a fragment of mispickel that had not been separated from the calaverite.

Before the publication of the discovery Huntley and MacIntyre had discussed it in all its bearings, and naturally saw in it the solution of the problem that for three years had puzzled mining men at Kalgoorlie, the source of the rich deposits of 'mustard' gold and 'sponge' gold that were so characteristic of the oxidized zone of the Boulder mines.

On June 1 the Block 45 mine was thronged with

assayers and others in quest of specimens of the new mineral, and a vigorous search for it was commenced at other mines. On June 4, J. Collet Moulden obtained at the Croesus mine assays of 13 oz. 15 dwt. gold from telluride ore that had been lying on the dump for months. A few days later Holroyd found rich telluride ore at the Australia mine (Associated Gold Mines), where it had been found in the shaft at a depth of 90 ft., but, having been mistaken for pyrite, had been thrown over the dump. Blocks of ore assaying more than 500 oz. per ton had been used as a fireplace in a miner's hut. Within a few months gold tellurides had been found at the Great Boulder, Hannan's Star, Lake View Consols, Golden Horse-Shoe, and Kalgurli mines. The Ivanhoe, South Kalgurli, Brownhill, and Oroya were the last of the important mines to find the ore.

On November 13, 1896, more than six months after the original discovery, gold telluride was obtained at a depth of 140 ft. in the Great Boulder Main Reef mine, then under the management of Modest Marijanski, a German mining engineer, who has, strangely enough, been hailed by the German press as the discoverer of telluride of gold in Kalgoorlie. Throughout these notices there sounds a note of self congratulation that by virtue of his thorough German training this engineer had made a discovery that had escaped the notice of his British colleagues, and also that the discovery had been made at a most auspicious moment, just in time to prevent the contemplated withdrawal of English capital from the West Australian mining industry!*

Later History

A very serious hindrance to progress in the earlier days of Kalgoorlie was the lack of fresh water both for domestic consumption and for mining and metallurgical purposes. The prompt assistance afforded by the West Australian Government in building a railway to Kalgoorlie and more particularly in furnishing an abundant supply of fresh water from a source near the coast and 350 miles away went far to remove the most insistent discomforts naturally attendant on life in the midst of an arid desert, and more important still from a mining point of view, materially reduced working costs. The history of the field has, on the whole, been one of continued prosperity, mitigated during the past few years by the exhaustion of the rich, easily accessible oxidized ores and by the restrictions in working the lower grade sulphide ore brought about by lack of cheap fuel and water, by distance from the seaboard, and by the high wages and the correspondingly high costs both of mine supplies and of living entailed by the current Australian canons of political economy. In technical practice the principal difficulties encountered at Kalgoorlie have arisen from the refractory nature of the ore, necessitating an enormous amount of experimental work with correspondingly large expenditure on new mill plants, as the older

methods become obsolete and uneconomical. At the present day both in mining and in milling methods, Kalgoorlie stands well in the forefront of modern practice. The weak feature in the former branch is the small size of shafts: this has not arisen from lack of knowledge or of foresight, but from the fact that there has never been a time when the prospects in depth warranted the enormous capital expenditure required for the substitution of the larger shafts. The greatest depth reached on the field is at the 2650-ft. level of the Great Boulder mine; the other six important mines of the belt are working near or below the 2000-ft. level.

The yield of the East Coolgardie goldfield (which has produced little gold outside Kalgoorlie) is shown in the following table. The gold yield of the state for corresponding years is attached to indicate the importance of the Kalgoorlie field.

Year.	Kalgoorlie.		Western Australia.	
	Crude oz.	Crude oz.	Value.	
1893	110,891	£	421,385

Dredging at Panama

The total excavation by dredges during May was greater than during any previous month since the beginning of canal construction. The total output from Atlantic and Pacific entrances was 1,522,102 cu. yd. Of this, 957,889 cu. yd. was from the Atlantic entrance channel; a large part of it, however, was in the removal of silt from the previously excavated channel. About 300,000 cu. yd. of this relatively light material was pumped out by the pipe-line suction dredge No. 4, operating opposite the mouth of the Mindi river, in the French canal. Excavation in the first district of the sixth division, covering the Pacific entrance channel and Balboa harbor, amounted to 564,213 cu. yd., about an average output for the fleet. The dipper dredge Cardenas established a local record for rock excavation in deep water. On June 4 it removed 1750 cu. yd. of hard rock from a depth of 45 ft. below mean sea-level in 9¾ hours of actual working time. On account of the great depth of the channel, the dredge is able to work only between mean ebb tide and mean rising tide, which allows two watches of five hours each.

The Olancho Country

By A. D. ARIN

No miner has ever been down the 'Spanish Main' who has not heard of the fabulous washings of the Guayape river, a stream in the mountains of Olancho, one of the departments of the Republic of Honduras. In this country, as well as the other little republics that make up the revolution-infested tail to the cornucopia of the North American continent, placer mining can never be mentioned without some one putting in a word concerning the great wealth in Olancho and the Guayape.

So when I was asked to go to Olancho, the gentleman who wanted some quartz reported on in that

was generally left to the women and children, who only work for a few hours on Sunday mornings. Yet the amount thus obtained and carried into Jutiualpa in the year 1853 was valued at \$129,600."

Dr. Charles Doratt, who visited the region in the year 1853, wrote in private letters: "Among the rivers of Olancho, which we visited and prospected, the Guayape and Jalan are decidedly the richest in auriferous sands. We found gold in the alluvions half a mile distant from the present bed of the river. Leaving Jutiualpa in a northeast direction * * * there is not a streamlet over an area

RIVER SCENE IN EASTERN HONDURAS.

district did not know what a favor he was conferring on me. In the interim I looked into the history of the country. To one who investigates the old Spanish writers, and some of the modern ones, it is refreshing to see how calmly they can tear the heart out of the truth and present you with the remains; but one can be charitable and suppose that they were assuming to give as first handed the tales that some one had told them.

Guayape Placers

E. G. Squire, in his admirable work, the most valuable published in the opinion of many people, says: "There can, however, be but little doubt that the gold washings of the rivers Guayape and Mangualili and their tributaries are equal in value to those of California. The principal supplies of this metal in the state are from the gold washings of Olancho, which are exceedingly productive. The river Guayape has always enjoyed great celebrity for the amount of gold contained in its sands; but, since the early period of Spanish occupancy, washing has not been carried on except on a small scale by the Indians, and even with them the process

twenty leagues long and ten broad, however insignificant, which does not contain gold in its sands and in the banks which border it. For the most part * * * these streams fall into the Guayape and Jalan." He also names the Sulaco, Cayminto, and Pacaya in Yoro as good placer ground, but I cannot agree with him as to the Sulaco, though I have had good pans at certain points on that stream.

Early Writers

So one might quote dozens of writers: Wells, Herrera, Juarro, Montiflore, Bailey, Bryne, Lombard, and others, but what is the use? They all are alike. So I will notice but one more, and that the honorable board of Frenchmen who formed a scientific commission from their Government to these regions, the results of their investigations being published by the Honduran Government in 1897. Among other things, they say: "The most famous rivers are the Guayape and Jalan, from where the Spaniards, during the colonial epoch, extracted fabulous quantities of gold. The quantity of gold exported, won in this manner (by *balca*.) varies annually from 750 to 1,250,000 francs, according to

the rainy season being more or less copious. Nuggets are frequently found weighing from one to seven or more ounces."

Crammed with information in four languages, I went to Olancho and went up the Guayape, first visiting the aforesaid gold prospect. I did not see the maidens and little children frisk down to the river on Sunday morning and extract enough of the yellow metal to buy next week's *frijoles* and *tortillas*, nor could I find that they had any particular affection for the Guayape, but I did find that they went long distances from their homes to places on the tributaries of the river and stayed there for months washing gold to support them during the dry season. I found that the matter of washing was not confined to the women and children, but is participated in by the men to the extent that they do their share of the excavation, the women doing the actual concentration and separation. These women are wonderful in their skill with a great, clumsy, wooden pan, and their muscular development is almost unbelievable.

Cost of Operation

There is comparatively little ground on the Guayape proper that can be washed without extensive and costly preparation, and I am frank to say that I believe some parts of it are absolutely inaccessible within the bounds of reason in cost. The native washes some gravel along the Guayape, picking out the bars and detritus after a rain that raises the river to flood stage. He simply skims the top, and anything like deep washing is unknown to him, as the deepest I have ever seen them work was about shoulder deep. They dig holes to this depth under the water, scoop up as much gravel as they can, and pass it out to the washer on the bank. This manner of working is now generally abandoned for reasons that can readily be realized by anyone who has ever attempted to shovel auriferous gravel from under water. A great part of the Guayape, in common with the other rivers of Olancho, is in a deep cañon. It is probable that the bottom of this cañon, where the gold is concentrated, is in many places not less than one hundred feet below the present river bed. Without surmising or stating the whys and wherefores of this conditions and others related, I will make a quotation which sums up the whole condition. A. T. Bryne, late engineer to the Government of Honduras, under date of November 15, 1888, says: "The mountain ranges show volcanic origin, and are generally composed of basalt, trachyte, porphyry, and granite with frequent limestone outcroppings. The hills and flats are for the most part composed of detrital matter of the Pliocene, or more recent origin. The hills are covered with clay and ferruginous loam; beneath this cap is the detrital matter, composed of conglomerates of fine sand, gravel, quartz, greenstone, shales, and all the metamorphic rock of the neighboring mountain ranges. Local stratification is frequently met, but there is no evidence of continuity of its bedding. The depth of the detrital mass is from 20 to 300 ft., the layers becoming coarser as the depth increases, the lower ones being composed of large boulders and gravel cemented together into

a hard and compact mass, resting directly upon the bedrock. This lower layer may properly be termed the paystreak. The bedrock varies in the different portions, being either chloritic slate, garnetiferous mica schist, secondary granite, gneiss, diorite, porphyry, and the various rocks of the Cambrian formation. The gold is found disseminated through the entire mass of these deposits." My personal observations accord with those of Mr. Bryne, and the individual supply is supplemented by the contributions of the streams that feed it. These cemented strata of detrital matter have always given me results sufficiently satisfactory to warrant the conclusion.

It is commonly said that placering is a poor man's business, but no poor man would do well to tackle it here. With sufficient money, properly applied, the working of these placers would be a tremendous enterprise and worthy of the mettle of any mining man. However, Olancho does not have to depend on its placers to be a mining country, for the veins bearing gold are numerous, and some of them are of surprising richness. Copper is abundant in places. One day an Indian brought some bullets whittled out of solid chalcocite. He said there was a vein of about four feet of the same metal. Crossing a little river only a couple of miles from the Guayape, is a vein of bitumen which melts and flows under the heat of the tropic sun. A short distance from this point are beds of nitre; and nearby native sulphur is found. Silver, of course, is present, and some nickel. Undoubtedly, careful prospecting will develop other minerals, for the country is an unknown land a short distance from the traveled roads, except in a few instances.

Evidence of Early Workings

Ruins of ancient civilization are common, and some of them are interesting. Many evidences of the Spanish occupation before the revolt of 1821 are to be found, and when one of their old mines is found, one generally finds something worth while, for in those days of crude mining methods there was no time wasted on low-grade. I know one mine that has been idle ever since the Spanish owners threw down their tools and fled before the advance of the enslaved peons, until two years ago, when the owner of the land was out hunting cattle and stumbled on one of the old dumps. Following this clue, it was found that the mine had extensive workings. For 90 years people have passed within speaking distance and the *lavaderos*, or gold washers, had a thousand times washed the sand of the little creek that runs at the foot of the hill, a hundred yards away. There are many of these old mines yet to be found, for there is not a village or hamlet but what has a store of traditions of these old mines, but the native is too indolent to look for what he does not see. The mine referred to above is one of the historic mines of the country and was worked by the Church.

The ruins of arrastres in certain localities are numerous. I have found as many as six within a five-minute walk. Wherever these arrastres are found, ore good enough to work in them will generally be found nearby. An old arrastre I know of

had no visible source of ore, but several hundred pounds lying beside it gave the key, and the lode was found, accidentally, a year later and over three miles away, but this was an exception, for the source of the ore is generally nearby. In some instances the arrastre was placed on the dump. I will venture to say that if fifty per cent of the money that has been spent in attempting to placer on the Guayape had been spent in quartz mining, the district would today be better known than the Klondike.

Working Conditions

Olancho is a poor man's country. Everything under the sun can be grown there and at all times of the year. Cattle are cheap, seven to eight dollars for a three or four-year-old with calf; timber is abundant and mainly pine, of which there are four varieties, including the long-leaved yellow; the temperature averages about 70°, and, ignoring solitude, all conditions are ideal, except accessibility for man and burden. Of course, man can ride in, but even as he comes in on muleback, the trip is a long and hard one as well as costly, but for those who undertake it properly and with sufficient capital, it is certain that reward lies in the hills and streams of Olancho.

The natives are, as a rule, friendly to 'gringos,' but occasionally one encounters a fanatic. I have found the people to be, with few exceptions, honest, obliging, and civil. With them the 'six-shooter' is a badge of gentility and station, and the *clat* that it gives secures many accommodations and civilities that I have seen denied those who sneered at the 'gun-packer.' I have had my gun rust until it stuck in the holster, and half the time did not know whether I had a cartridge or not. On the whole, the gun is a very useful part of one's kit, sometimes, but the American one occasionally meets there who is always flourishing his gun and trying to make an impression is an object of contempt to the native and pity to his better-balanced countrymen. He is the class of man who makes the rough places in the road for those who follow him.

Americans as a rule have not been very successful in Olancho. A notable exception is Fred Bell. With placer, arrastre, and buying gold from the native washers, he has been extremely successful, while working on a very modest scale. What he has done, others can do, for his operations have been confined to a zone that is not by any means the only good ground in Olancho.

Weight Standards

Troy balances for weighing dust are not accepted in this country, as they only recognize the Spanish ounce, the subdivisions of which are represented by pebbles and coins. They standardize these weights by comparison with some that are reputed to be correct, and as these are generally owned by the local dealer, who makes sure that they do not rob him, everyone is satisfied.

To analyze the cause for failure of Americans in this field would require several reams of paper. The key to the real cause, without individualizing, can be summed up in a few words: ignorance of local

conditions, ignorance of mining, graft, and rascality; either, any, or all. The successful men have emphasized the truth of this, and it is hard to believe that a well balanced, competent mining man, speaking the language, knowing the country, people, and conditions, backed by reasonable capital and with an honest desire to do a legitimate business, can fail in this country of opportunities. Every instance of failure that has come to my notice has had ignorance or graft behind it as the primal cause.

One man spent \$20,000 on miles of ditch to bring an insufficient water-supply to sluice away 40 ft. of clay overburden, and after completing the work found that he not only did not have sufficient water to do anything, but that, also, he had no tailing ground. Another company spent thousands in bringing water and a fine outfit, to discover, when all was ready, that the entire equipment was valueless owing to plain physical conditions apparent to the most casual and non-technical observer. A dozen companies have gone broke because they tried to bring in machinery that no pack-mule in the country could carry. They evidently knew nothing of the merits of sectionalized machines, and as a result the great pieces of iron lie rusting on the coast, unheeded warnings to many who have come after.

I cannot understand the motive that leads men to believe that it takes less skill and experience to operate in these countries than at home, but it seems to be a popular idea. These men, predestined to failure, seem to have an idea that all that is necessary is to carry into the country a varied assortment of mining machinery, select a place to go to work, and success is certain. The results are natural, and they go away spreading detrimental reports in which they are ably abetted by the unfortunates who financed them.

Natural Advantages

The apparent mineral riches, the amenability of the greater part of the ores to treatment, the cheap water-power that exists within transmitting distance of most points, and a thorough understanding of the governing conditions prompts me in saying that I know of no district where there are greater possibilities for intelligent and properly applied mining effort. It is practically untouched, for the native, as a rule, knows the placer only and the large majority of foreigners have followed his lead. The native's placering is, of course, primitive, and the results he attains are commensurate. He is limited to what he can do with his hands and the batea. As an example, I might describe one outfit out of the many that I have seen. The party consisted of a man and four women. They had come forty miles, from Jutigalpa to the Lavaderas, there erected huts to live in. They were removing a heavy overburden, carrying the pay-dirt to a water-hole in a ravine some 300 yd. distant, and washing it. They did not average over sixty cents per day to the person, but seemed to think they were doing well. As the stranger cannot live on what the native hoards, he quickly pronounces the whole country a farce. Disgustedly he classes the quartz with the placer and leaves the country. There is good

quartz in Olancho, and intelligent prospecting will develop more, for aside from certain restricted areas, no one has left the highways to prospect. The native, as a rule, has no knowledge of hard formations. I met some natives on the Mangualili grinding a soft honeycombed quartz on a *metate*, or between two rocks. The quartz was well filled with coarse gold. They said the vein was about two inches wide; but as to where it might be, I thought it impolitic to ask. Prospecting one day in the valley of the Panal, I came across some mounds of ore, dirt-covered and grass-grown. A little farther on, beside the creek, was a group of *metates*, half buried in the soil, most of them just as the workmen had left them, probably to take part in the revolution for independence from the Spanish oppressor. Just across the stream was an old *arrastre*.

The Water Question

The water question is an ever-present one in all districts. In most districts of Olancho, water is present in streams sufficiently available for all purposes where capital is to be had to canal it to the workings, but many good placer grounds are too far away from a sufficient supply for operation by men of modest means. There is probably no locality in the department where ample water for milling purposes cannot be had, and there is no locality I know of but that is within reasonable distance of power. I visited one locality where it was reputed no power was available, but a short search proved that there was an available head of 500 ft., ample water for a dozen mines, with not over five miles to transmit the energy. This was an exceptional case, but as a rule, wherever a sufficient volume of water is found, the rapid drop of the valleys quickly makes the head. The eroded channels make numerous, excellent, short-crested dam-sites, with material for construction close at hand. A necessary warning to those contemplating entering the country is that they be sure that the stream they select is one of sufficient volume in the dry season, for many of the streams go almost if not entirely dry at certain seasons. The only way to be sure is by actual observation, for the natives cannot be trusted in this particular. The difference between what is really necessary and their idea of it varies so that absolutely no reliance can be placed on their estimates. Generating power at a point away from the point of consumption and transmitting it in the form of electric energy is far preferable to attempting to put in steam-power at points where water-power is not immediately available. To be sure, there is wood in abundance (the country is covered with forests), but getting in the heavy units required for a steam plant is almost prohibitive.

Exports of iron and steel products from England during the first five months of 1913 amounted to \$112,300,000, an increase of \$25,270,000 over the same period of 1912.

The Minster-Grenchenberg tunnel being driven under the Jura, in Germany, is giving considerable trouble caused by great pressure in the upper Miocene formation.

The McIntyre-Porcupine Mill

The following description of the 150-ton plant is abstracted from the annual report of the McIntyre-Porcupine Mines, Limited:

The ore is hoisted into an ore-bin. From this it is fed to a 10 by 12-in. Blake crusher, over a grizzly with bars $1\frac{1}{4}$ in. apart. The undersize joins the broken ore from the crusher and falls into a 12-in. elevator, which raises it to a hopper, from which it is automatically fed to a 16 by 36-in. set of rolls. The rolls discharge the ore to a 12-in. elevator 50 ft. long, and is then hoisted to a 500-ton storage-bin. From there it is fed to a 6-ft. Chilean mill by means of a Challenge feeder. Four tons of cyanide solution, of a strength of $1\frac{1}{4}$ lb. per ton, is added to the Chilean mill for each ton of ore ground. The Chilean mill discharges the ore through a six-mesh screen to a Colbath classifier, which then discharges all ore over 100 mesh to the tube-mill. Ore finer than 100 mesh flows over the end of the classifier to a 16 by 24-ft. thickener. The tube-mill discharges the ground ore to a Frenier pump, which elevates it to a hydraulic classifier. This returns the free gold that may have passed through the tube-mill, and the sulphides, coarser than 100 mesh, are again returned to the head of the Colbath classifier, which is supposed to retain, in the closed tube-mill circuit, the free gold and the coarse sulphides which contain most of the metal content of the ore.

The overflow from the hydraulic classifier joins the overflow from the Colbath classifier and flows to the thickener mentioned. The proportion of the cyanide solution to the ore, at this point, is five to one; one ton of dilution being added at the Colbath classifier and tube-mill. The thickener discharges, over the top, three tons of clear cyanide solution to each ton of ore fed in. This solution contains about 75% of the total gold in the ore, and is sent to a 12 by 20-ft. clarifying tank, to remove any traces of slime which may escape the thickener. Each ton of ore, with the other two tons of cyanide solution, fed to the thickener, is then discharged at the bottom to a 16 by 24-ft. agitator, which discharges continuously to a 20 by 24-ft. thickener and slime-storage tank. At the bottom of this tank each ton of pulp is discharged with one ton of cyanide solution, which then is elevated to a 16-ton tank at the top of the mill, from which the Burt filters are filled. A cake, ranging from 2 to 5 in. thick, is formed in the filter, which contains about 20% of the gold-bearing solution, and after extracting this the doors of the filters are opened and the cake is discharged. The gold solution from the clarifying tank flows through five 7-compartment zinc-boxes, where the gold is precipitated on zinc shaving and the solution passes into two tanks to be used as barren wash for the Burt filters. The precipitate is cleaned from the zinc shaving and sent to a tank. All solutions go to a 20 by 30-ft. concrete sump under the Burt filters, and from there are returned, by two triplex pumps, to two 16 by 20-ft. cyanide storage tanks situated at the top of the mill, where they are tested for loss of cyanide.

A Simple Plant for Testing Efficiency

By A. T. TYE

The Cananea Copper Co. maintains a sampling and testing plant at its concentrator at which any new ores may be tested as to concentrating qualities. These tests indicate clearly the relative economy of smelting or of concentration followed by smelting. As any number of carloads can be handled at the sampling plant, a representative sample of a 400 to 600-ton lot can be secured without any additional expense or trouble.

The crude ore crushed to one inch is first sampled by a bucket sampler with a ratio of 35 to 1. This sample is then crushed in 14 by 27-in. rolls and sampled by a second Snyder machine, ratio 5 to 1; crushed in 14 by 27-in. rolls, ground in a sample

the water and slime from same delivered into tank (F) to be pumped to the vanner (I) together with the Wilfley tailing and slime. The concentrate is run low in silica if the mine is at a great distance from the smelter, or fairly silicious if the concentrate contains considerable iron and sulphur and when the smelter is in close proximity to the concentrators, as at Cananea. In every way, the tests are made to conform to actual milling conditions.

Sand and Slime

The coarse sand and slime are discharged at (B) and are delivered into tank (D), from which the coarse tailing is finally discharged at (E), dried, weighed, and sampled. The slime overflows from (D) into tank (F), from which it is pumped to the vanner (I) by a centrifugal pump (G) run by 1/2-hp. motor (H). The slime is concentrated on an ordinary mill vanner and the concentrate collected in (J), and dried, weighed, sampled, and assayed. The tailing from the vanner is the only material not weighed directly, and it is determined by difference. All the remainder of the products are carefully dried, weighed, cut down, and assayed in duplicate. The final vanner tailing is carefully sampled every three minutes, as this is a final check on all former weights and assays. Tank (D) is filled with water before starting, so that the coarse sand settles out and slime is at once discharged to the vanner feed.

	0.65	0.28	0.44

The tailings represented are from a tonnage of 500 to 1400 per day. At the Cananea concentrators, the ore comes from a great many different orebodies, so that unless treated in a separate section, the feed nearly always contains a mixture of different ores. For this reason it is difficult to obtain tailing in actual ore-dressing, from one ore only. The copper in the feed may vary from a little over 1% to over 3%; the iron from 5 to 20; sulphur from 5 to 20; and insoluble 49 to 83%. But, as shown above, the tailing from entire sections of the concentrators agrees closely with that obtained in the tests, and this holds true for other ores, when they have been concentrated without intermixture.

Separate tests are made on each ore every month to credit the different mines with the amount of copper they have added to production and to determine what grade of ore must be mined to pay all expenses of mining, transportation, concentration, smelting, and losses. Diagrams are constructed which show the actual profit above all expenses, so that the profit can be read off at once for whatever grade of ore is being mined.

Composite Tests

From every sample of crude ore brought to the concentrator, 15 kg. of the final sample is weighed, dried, and pulverized, and deposited in large dust-proof boxes. At the end of the month this ground ore is riffled down until 100 kg. remains, and this serves as the basis of the test of each separate ore.

TABLE III.—COMPARISON OF RESULTS FOR JANUARY

	Smelter office, %.	Concentrator office, %.	Composite test, %.
Moisture in concentrate....	15.05	13.45	13.70
Cu in ore	2.22	2.22	2.22
Cu in concentrate	6.17	6.27	6.05
Cu in tailing	0.83	0.76	0.82
Extraction	72.31	74.85	72.88
Ratio	3.84	3.77	3.73

Besides these separate tests, a composite mill-test is made of all the ores milled during the month, mixed in the same proportion as milled. This is done for several reasons. It gives a criterion by which to judge the work of the concentrators. The results indicate in concrete form the general tailing, feed,

extraction, etc., and show what extraction should be shown by the credits from the smelter receipts of concentrates.

January Results

Results of comparisons for January 1913 are shown in Table II, based upon price of copper 17c. per pound with 96% saved in smelting, or 16.3c. per pound. The cost of smelting, including fuel, power, labor, supplies, repairs, salaries, general expenses, sampling, roasting, converting, fluxes, fettling, amortization, interest, transportation, refining, freight, and selling, is taken at \$3.10 per ton. Ratio of concentration, 5.6 into 1. Therefore, the cost of smelting the concentrate per ton of crude ore is \$0.55. Cost of concentration, \$0.72 per ton. Cost of mining, \$1 per ton. Total expenses per ton of crude

ore, \$2.27. Crude ore assaying 1.48% Cu gives an extraction of 78.8%, or 23.32 lb. at 16.3c., equal to \$3.80 less \$2.27 expenses, leaving \$1.53 profit per ton. Crude ore assaying 1% Cu gives an extraction of 68.5%, or 13.7 lb. saved at 16.3c. per lb., equaling \$2.23, less cost \$2.27, leaving a loss of \$0.04 per ton. Therefore the critical point between profit and loss is at 1.03% Cu in the feed, as per diagram.

It would require a great part of the time of an office man during the month to tabulate and calculate the tons of wet ore, tons of dry ore, tons of dry concentrate, and similar data from all the mines and concentrators, and to note all the various deductions, to determine the average of the ore, of concentrate, tons of copper in the feed, tailing, and concentrate, and the extraction. The same results can be determined by a monthly composite test requiring less than two hours.

It might appear that close results could not be obtained in this manner, that from only 100 kg. of ore the same results could not be determined as by actually milling 66,000 tons of ore per month. And yet it is the same comparison as between an assay-ton weight of pulp and a thousand tons of ore which it represents. If the ore has been properly cut down and quartered, the assay of the few grams of pulp will indicate accurately the contents of the thousand tons of ore. Likewise the 100 kg. will give the same comparative results as the concentration of thousands of tons in the various sections of the concentrator.

What a concentrator actually recovers is not nec-

essarily the calculated total; it is the tons of copper the smelter actually credits it with. Therefore, comparing the extraction shown by the composite tests over several months with what is actually acknowledged by the smelter, as the tons of copper received as in Table III, shows the accuracy of the composite tests. There is a slight variation from month to month, as all the concentrate produced some months ago may not be shipped and is credited to the following months.

TABLE IV

Month.	Extraction.	
	Composite.	Smelter.
January	75.00	74.69
February	75.50	73.95
March	72.60	71.15
April	76.60	77.50
May	73.80	72.60
Average	75.00	74.00

The composite cheeks within 1% of the smelter returns, which difference is partly covered by loss in transit and variations in concentrate moisture determinations. This is as close as can be calculated from the crude ores and concentrates with their various assays and moisture determinations. In calculating the results, the percentage of moisture in the concentrates delivered to the smelter is likely to be the most prolific source of error, and the credits to the concentrator vary accordingly. With disseminated porphyry ores, the average concentrate sample per shift or day can be accurately determined, which, with the feed and general tailing, gives the necessary data for calculating the rates and saving. At Cananea, however, with coarse bull-jig and fine concentrate mixed, it is almost impossible to obtain such a sample, and each carload of concentrate is sampled separately.

Standard v. Miniature Machines

Possibly the majority of mining men are of the belief that a concentration test on a new ore cannot be made on a small scale, and if so, that the testing plant must contain miniature jigs, classifiers, tables, and vanners. The difficulty with so many small machines is the error incurred in starting and cleaning-up afterward, and the additional doubt whether, after all, the small machines do duplicate the work of the larger machines in mills. For this reason, at Cananea, the tests are made on a regular full-sized Wilfley table and vanner which at other times are used in everyday work, and in the same state of repair as the general average. With these machines, the test gets under way rapidly and is finished quickly. The greater part of the time the machine is running as in ordinary millwork. The Wilfley acts as a classifier, as also the settling-tanks. The coarse grains of concentrate protect the finer grains, and the latter are saved along with the coarse, thus relieving the vanner of part of the load and making up in part for lack of classification and stage-crushing. The Wilfley and vanner also get more individual attention than in a concentrator, so that, on the whole, there is a series of compensations which about equalizes different conditions. If tests on small lots of ore have not been successful, it is probably on account of carelessness in not secur-

ing a really representative sample from the mine, and not the fault of the testing plant.

Conclusions

1. This method of testing has been in use for several years at Cananea.
2. It has been successfully tried out on a great variety of ores.
3. Compared month by month with tonnage up to 66,000 per month, it has given results within 1% of actual smelter returns.
4. The machines used are full-sized standard Wilfley and vanner machines.
5. The machines employed in testing are those used every day in regular mill work and in the average state of repairs.
6. The testing plant can be fitted up at small expense in almost any concentrating plant.
7. New orebodies, or regular ores at greater depths can be tested and their behavior in large concentrators milling thousands of tons may be determined very closely. Even in large units the tailing and other products will vary somewhat from day to day.
8. These tests quickly give accurate data for reports on mining property as to the probable behavior of an ore, and give valuable information which may serve as the basis of experiments in a large testing works.

Thanks are due to F. J. Straehan, superintendent of the Cananea concentrators, for permission to publish the foregoing data.

Kleinfontein and Tube-Mills

The annual report of the Kleinfontein mine for the year 1912 contains some interesting features supplied by the consulting engineer on the results of development and the value of the tube-mill as an adjunct to the stamps. It is stated that the stamp and tube-mill combination introduced as an expediency last year has not been such a success as generally supposed for the reduction of costs, which, since the introduction of tube-mills, have increased from 4s. 2d. per ton with stamps only, to 4s. 5d. per ton with stamps and tube-mills combined, while the percentage of extraction has fallen from 95.79 to 94.60. It need hardly have been pointed out that these unsatisfactory results of the introduction of tube-mills are not the rule on the Rand, for generally the costs are lowered and the extraction percentage is increased by the addition of tube-mills. One group by employing 15 stamps only to one tube-mill can handle the same tonnage as that at New Kleinfontein at a shilling per ton less in cost, and moreover are introducing tube-mills so as to attain this proportion with the direct aim of hanging up stamps because they are less efficient and economical than tube-mills. The Barnato group, too, find that the addition of tube-mills last year added considerably to the efficiency of the mill, using stamps solely, as well as to the extraction.

Expenditures on the Panama canal during the year ended June 30, 1913, amounted to \$41,741,000, making a total of \$318,229,000.

Searles Lake Potash Deposits

By H. S. GALE

*Searles lake, also known as Borax flat, is a dry lake basin and superficially much like many other desert basins of the Western arid regions. It is a broad somewhat circular valley or depression lying between the Slate and Argus ranges in the extreme northwestern part of San Bernardino county, California, near the corner between that county and Kern and Inyo counties. The camp known as 'The Borax' is about 25 miles by road from Searles post-office, formerly Garden station, near the Mohave-Owenyo branch of the Southern Pacific railroad. Searles lake at present may be reached by the regular stage that runs from Johannesburg *via* Garden station, or Searles, to Searles lake, and thence on to Ballarat and Skidoo.

Analysis of Brine

The public announcement of Searles lake as a possible source of potash was made as the result of the collection and analysis of a representative set of brine samples from this deposit early in March 1912, by E. E. Free, then of the United States Bureau of Soils, and Hoyt S. Gale, of the United States Geological Survey. A notice was at that time given to the press stating that reports which had been received concerning the unusually high potash content of the brine in the deposit were apparently confirmed by the results of these tests. Analyses of six brine samples taken at considerable depth in old wells at points distributed over the main salt flats showed that an average of 6.78% of the total dissolved salts was potash, quoted in the form of the oxide (10.73% as potassium chloride). The individual results obtained were 7.63, 6.23, 6.89, 6.06, 7.27, and 6.57%. The uniformity of these results was taken to indicate, although of course it did not prove, homogeneity in composition of the brine throughout the salt deposit. Based in part on the logs of the wells that had already been drilled, the statement was also made at that time that "existing data give reasonable assurance that the brine-saturated salt body is at least 60 ft. thick and covers an area of at least 11 square miles. Assuming the salt to contain 25% by volume of the brine, the total amount of potassium oxide available is estimated as over 4,000,000 short tons [equivalent to approximately 6,000,000 tons as potassium chloride]. This estimate is based on incomplete data, but it is believed to be conservative. At any rate it appears that this locality constitutes a very important source of potash in readily available [soluble] commercial form." Whether it will be possible to recover all of this potassium commercially, however, must remain for practical experience to demonstrate. There seems to be good reason for the belief that the commercial operation of this deposit for potash and the other marketable salts that it contains will become a large and important enterprise. Probably

the first chemist to suggest that potash might become one of the profitable products of this deposit was Whitman Symmes, a mining engineer of California and Nevada, who in 1898 was superintendent of the California Borax Co., operating at Searles lake.

Nature of the Deposits

The saline deposit at Searles lake resembles a typical playa, of which examples are common in the desert basin region. The salt-incrusted surface occupies the lowest part of the valley or basin in which it is situated. The drainage basin tributary to it is without outlet, so that if the basin were filled the water would rise to a height of approximately 640 ft. above the level of the present salt flat before it would find an outlet and overflow into the Panamint valley to the south and east. That the valley was thus flooded at some time in the past is attested by the series of shore lines to be seen encircling the basin, the highest clearly marked reaching the elevation of the present lowest divide on the southern margin with successively lower concentric shore lines, marking the recession of the waters as they evaporated and as the lake level subsided. The saline deposit in the lowest part of this basin is the residual product of the evaporation of natural drainage waters.

It appears at this time to be quite clear that the greater part of the water of the former higher level of Searles lake was derived by overflow from Owens lake and hence came chiefly from Owens river. All natural river waters contain some dissolved salts. By long-continued accumulation within a restricted basin from which little or no water is lost by overflow and the water disappears by evaporation alone, the solutions become gradually more and more concentrated with salts, and eventually if the lake approaches complete dryness these salts are deposited as a more or less massive crystalline body. This is evidently what has taken place in the basin of Searles lake. The final evaporation of this large lake is supposed to have resulted from the failure of the principal source of its water supply, when possibly with a general lowering of humidity of climate a slight decrease in the flow of Owens river caused Owens lake to cease to overflow the divide on its south side.

Structure

The physical status of the main saline deposit in the bed of Searles lake today is revealed by a large number of borings that have been put down by private interests in various explorations of the salt beds and by the analyses that have been made from them. So far as has been determined, the main salt body appears to be a bed at least 11 or 12 square miles in extent and having a depth of 60 to 70 ft. A much greater quantity of salts doubtless exists beyond the central area of the more solid salt mass thus defined. This body of salts is chiefly crystalline, in part compact, but in general is be-

*From advance chapter on potash in 'Mineral Resources of the United States for 1912,' published by the United States Geological Survey.

lieved to be of cellular or open erystalline structure, being really a body of salts standing in the residual brine from which it has erystallized. Experiments in the wells that have been put down appear to show that this brine is in nearly all parts of the salt bed free to flow and that it stands high in the deposit, approximately at the actual surface of the salts. Thus the brine constitutes the ground-water level of this part of the basin, occasionally after wet periods flooding to a shallow depth over the surface, but generally dispelled by the rapid evaporation of this dry elinate until its level sinks below the reflecting white surface of the salt crust. Evaporation at this surface is presumably continuous, the body of the ground water being as continuously replaced by inward seepage from the marginal alluvial slopes. Little sediment other than wind-blown dust is ever spread out upon the main salt plain by the occasional floods, and the salt of the central part of the deposit appears white or tinged with pink and for the most part comparatively clean.

Composition

Many analytical data as to the composition of the mass of erystallized salts of this deposit are in existence. On the salt as distinguished from the brine, which will hereafter be discussed, the Survey has at present no original data, for they could be had only from carefully collected samples obtained during the drilling in the deposits. There is good reason to believe, however, that the salts as well as the brine contain a considerable percentage of potash. Some of the private analyses from this deposit have been made public in a recent article. Several analyses, chiefly of the brine, have been made by the government bureaus and should give accurate data as to the composition of this part of the deposit. The following are the more complete analyses of the brine made from the samples collected at Searles lake March 6, 1912, now published for the first time:

salts that might be derived therefrom the following result is obtained. This is the approximate composition of the anhydrous residue which results from the complete desiccation of the brine.

HYPOTHETICAL AVERAGE COMPOSITION OF ANHYDROUS RESIDUE OF BRINE FROM SEARLES LAKE BASIN	
	Per cent.
Sodium chloride (NaCl)	51.61
Sodium sulphate (Na ₂ SO ₄)	19.22
Sodium carbonate (Na ₂ CO ₃)	12.79
Sodium baborate (Na ₂ B ₄ O ₇)	3.23
Potassium chloride (KCl)	12.07
Sodium arsenate (Na ₃ AsO ₄)	0.17
	99.09

The original brine contains a variable percentage of bicarbonate, which is converted to the carbonate form in the anhydrous residue and is so expressed.

As is well known, the theoretial composition of salts in the brine, as shown by the calculations from the analyses, can be accepted as a working basis only with certain reservations. Doubtless most of the salts named in the conventional method of computing the analysis of a solution may be abstracted from the brine somewhat in the proportions given, provided that satisfactory chemical proecesses can be devised to accomplish the desired result. It is believed that this has already been at least partly accomplished experimentally. But it is also true that no practical process of extraction on a commercial scale will derive all these salts in the amounts shown.

Working Plans

Estimates of other available constituents similar to the estimate of the total available potash in the deposit can be readily computed on the basis of analyses of the salts and the brine. At present the plans for working the deposit contemplate the manufacture of the salts from the brine, which, as a liquid capable of being pumped from place to place, is more readily susceptible of manipulation than the solid salts. Preliminary estimates of quantity

B ₂ O ₃	3.07	1.58	1.77	2.03	2.08	4.14	2.45
Total	98.42	97.48	97.52	97.46	98.70	99.57	98.20
Total salts (Ignited residue, percentage of original sample)	33.48	33.94	33.30	32.96	33.21	32.88	33.30
Specific gravity	1.3002	1.3045	1.2969	1.2935	1.2959	1.2932	1.2974

Each sample was collected by lowering a stoppered and weighted bottle to a depth of 35 to 40 ft. in the brine and then, by means of a separate cord provided for the purpose, jerking out the stopper and allowing the bottle to fill.

By recalculating the average results of these six analyses to a theoretial or possible combination of

of production have been made on the basis of the composition of the brine and on an assured constancy of composition under continued pumping. As to the composition of the brine, the analyses here quoted are now available, and as to the constancy of the brine under pumping, there is opportunity for experimental verification of hypotheses.

It is recognized that, in general composition, desert basin salines are quite distinct from salines that have been produced by the desiccation of marine waters. The Stassfurt salts are similar to the deposits that would be left by the evaporation of normal sea-waters. They contain soluble magnesium salts as an important constituent, especially in conjunction with the potash-rich portions of the deposits. Most of the desert basin salines in the United States are more or less of the Searles lake type—that is, they are composed largely of chlorides, but contain considerable proportions of sulphates and carbonates, chiefly of sodium with some potassium, and little or no soluble magnesium salts. The desert basin salts may be described as salines derived by the direct leaching of continental areas, as distinguished from salts of direct marine origin. Ultimately both classes may be said to have had a common origin.

It is still too early to offer any general summary statement regarding the industrial situation at Searles lake. An immense mass of salts and an equally great volume of saturated residual brine exist in this deposit. The compositions of the salt and brine are fairly well determined. Several of the ingredients which could be extracted have an established value in the chemical markets generally, and some, like sodium sulphate, have potential value.

Withdrawal from Entry

The lands at Searles lake were withdrawn from entry by an order approved February 21, 1913. This withdrawal is not intended to interfere with any valid mining claims that existed prior to the withdrawal, a fact that is made clear in the express wording of the order itself: "This withdrawal is made subject to all rights lawfully initiated under any valid mining locations made upon such lands so long as such rights are maintained in full compliance with the law." In order to relieve the existing uncertainties regarding the validity of 'potash' or general placer locations carrying saline deposits in large area, a draft of a law has been prepared and submitted to the appropriate committee in Congress, which it is believed will provide a satisfactory title basis under which such lands can be worked. It is to be hoped that in the interest of a possible American potash production the matter may receive due consideration and that enactment of a proper measure to this end may be accomplished.

Iron Production for 1912

The iron ore mined in the United States in 1912 amounted to the great total of 55,150,147 long tons, compared with 43,876,552 tons mined in 1911, an increase of 11,273,595 tons, or 25.69%, according to an advance statement by Ernest F. Burchard, of the United States Geological Survey. The production for 1912 was second only to the output of 1910, falling 1,864,759 tons below the record production of that year, which was 57,014,906 long tons.

The Minnesota iron ranges are producing at present considerably more iron ore than is produced in all the rest of the states together, having furnished

nearly 62.5% of the total for the United States in all the mines in Minnesota and Michigan and part of those in Wisconsin, mined 46,368,878 tons in 1912, or nearly 84.08% of the total.

The total quantity of ore marketed in 1912, according to reports received by the Survey, was 57,017,614 tons, valued at \$107,050,153, compared with 41,092,447 tons, valued at \$86,716,575, in 1911. The marketed production, therefore, represents an increase in quantity of 15,925,167 tons, or 38.75%, and in value of \$20,333,578, or 23.45%. The average price per ton in 1912, according to these figures, was \$1.88, compared with \$2.11 in 1911. According to the reports of producers, many of which have been somewhat revised since the report for 1911 was published, the total quantity of iron ore in stock at the mines at the close of 1912 amounted to 10,241,287 tons, compared with 12,206,390 tons at the close of 1911, a reduction of 1,965,103 long tons, or 16.1%, which balances closely with the excess of sales over quantity mined.

Gravel Plant in Nevada

The following is a description of T. Wilson's plant in operation in the main Manhattan gulch, as published in the *Manhattan Post*. The main feature about the hoisting machinery is an endless double-chain elevator with shallow buckets every two feet, the two chains making an elevator about 20 in. wide. This hoists the gravel from a feed-bin of 35 cu. yd. capacity, at the bottom of the shaft, on bed-rock, 65 ft. below the collar of the shaft, up to a storage-bin which holds about 25 cu. yd. of gravel, this bin being about 25 ft. above the surface. From the storage-bin the gravel is sluiced whenever sufficient yardage has accumulated. From the chute of the storage-bin, the gravel falls into a revolving trommel made of heavy screen of sufficient mesh to allow rock of 1½ inches in size to fall through, the oversize working out at the lower end into a chute and from there to the waste pile. A steady stream of water is played on the trommel, washing the loose clay from the rocks and gravel which holds the gold. Directly below the trommel is the shaker, a box similar to a sluice-box, but with deep riffles, crosswise, every 2 in. of its 12-ft. length. By means of an ingenious system of pivots, this box is rapidly shaken, with a play of about three inches, endwise, and an inch up and down. At the lip of the shaker three small copper plates are fixed. The gravel falls from the shaker, passes over these plates, and any fine light gold which will not settle readily between the riffles becomes amalgamated with the quicksilver on the plates, and then is soon caught by the lower riffles. Below the plates a line of sluice-boxes, all containing riffles, some cross and some lengthwise with the boxes, extends for about 150 ft. The small percentage of gold which escapes the shaker box is caught in the travel down these boxes. Mr. Wilson estimates that over 90% of the gold is caught by the shaker. The power for the elevator, trommel, and shaker is obtained from a 15-hp. Westinghouse motor. About 15,000 gal. of water is added to the supply each day.

Relation of Faulting and Mineralization in Goldfield

By CORRIN BARNES and E. A. BYLER

That portion of the Goldfield mining district which has so far proved the most productive, includes the Goldfield Consolidated and Florence mines, and it is here intended to point out the relation existing between the Columbia Mountain fault and this mineralization.

System of Fissuring

F. L. Ransome, in his report on the Goldfield district, suggested a relation between this fault and

appears beneath the dacite. It may be followed underground from here fairly close to its southern end, by means of the relative positions of the different formations, as disclosed in the underground workings. Its approximate position on the surface south of the Red Top is indicated on the map by a dotted line.

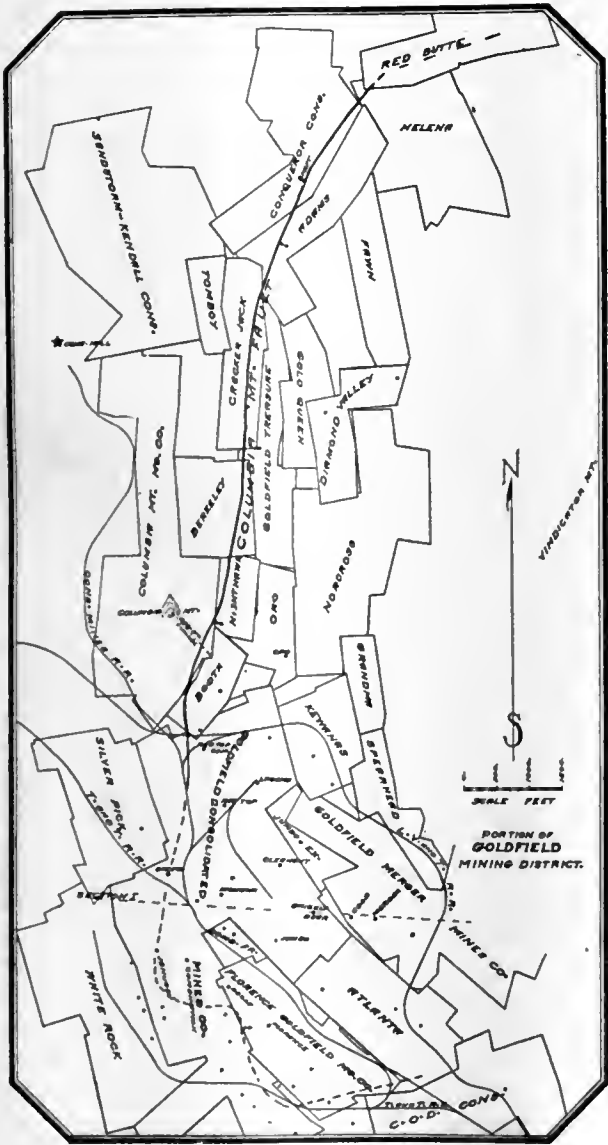

Between the January and the Florence it makes a sharp bend to the east, and then again to the south to its southern extremity, where it ends at an east-west fault. At its northern extremity the manner of its ending has not been disclosed, but it appears here also to end at an east-west fault which probably extends to Diamondfield. The dip of the fault is to the east, all that part north from the January having a regular dip, averaging about 28 degrees. From the Florence south the dip is much steeper to the east, the amount of which has not as yet been determined, but is probably about 60 degrees.

Mr. Ransome has concluded that the main movement of the Columbia Mountain fault was prior to the dacite intrusion, and that it occurred in the andesite and in the underlying rocks. Then came the intrusion of the dacite through the latite, to the fault and across it, and into the latite-andesite contact, lifting up the andesite which has in places since been eroded leaving the dacite at the surface. This conclusion has been disputed by some, but there seems abundance of evidence to support it, and Ransome's idea is now generally accepted.

Situation of Fault Zone

Section I, as shown in the illustration, is through the Mohawk, Grizzly Bear, and Merger Mines Co. shafts. This section furnishes data for a close location of the fault zone on its dip, and work now in progress on the Grizzly Bear and the shaft of the Merger Mines Co. will still further demonstrate it. The fault zone, shown in this section on its dip, is approximately the sloping fault-contacts of dacite with latite, and latite with shale, and at deeper workings probably the fault-contact of shale with alaskite. The downward throw on the east side of the fault has not been sufficient in amount to allow the approximately horizontal layers of latite and shale to entirely pass their corresponding layers on the west side; therefore, the fault zone in places passes through latite upon both sides, and similarly through shale. In consequence of the dacite intrusion across this fault along a portion of its length, which practically obliterated it to a depth of some three hundred feet, it follows that the relative position of the geological formations caused by the fault do not properly show above or at this intrusion, though they do below it.

After the dacite intrusion, there has been a further small movement along this fault zone, and where the intruded dacite lies across the upward extension of the zone, no pre-existing fracture is present; and the movement, while following in general the extension, has been recorded in irregular

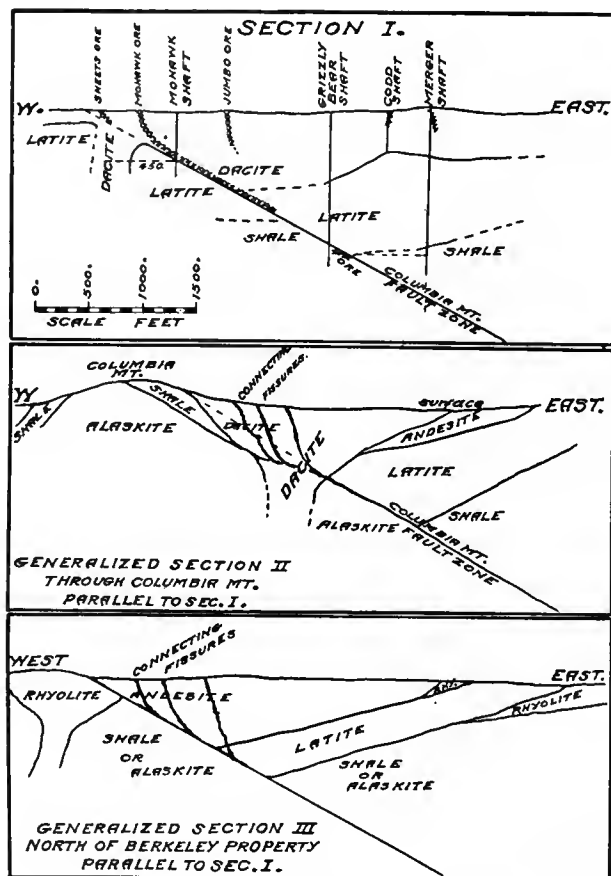

GOLDFIELD DISTRICT.

the ore deposits of this portion of the district, but while the extent and character of the fault were well demonstrated, there was not at that time sufficient development in the underground workings to determine its relation to the ore deposits. Later developments have furnished information from which this relation may be deduced, and the general system of mineralization outlined.

This fault, as shown on the plan map, is traceable along the surface from its northern end near the Conqueror mine shaft, south a distance of some two miles to the vicinity of the Red Top, where it dis-

fractures extending upward to the surface, having a steeper dip and connecting below with the fault as shown in section I. The mass of eruptives and solidified dacite intrusion has settled irregularly, due to the additional movement of the fault in its original position below, and we consequently find many irregular fractures extending from this fault zone to the surface. These fractures connect below and finally with depth merge with the original fault zone; the foot-wall of which in effect forms the foot-wall of the mineralization.

SECTIONS THROUGH FAULT ZONE.

South of the January, where the fault makes a sharp bend to the east, there seems a probability of the existence of a cross-fault which would account for the difference in dip of the fault north and south of this bend. There is some evidence that this follows the east-west contact between the dacite and andesite. There is, however, no conclusive proof of the existence of this cross-fault, as there are insufficient workings penetrating the latite, in which formation would be recorded the entire movement, while in the dacite above would only be recorded the later small movement subsequent to the dacite intrusion, which may have been distributed in such a way as to make its existence not apparent.

As shown in section I, a cross-cut west from the Mohawk shaft on the 450-ft. level penetrates a body of dacite, the position of which indicates that it is a dike, and while there are not workings enough at proper depth to the north to prove it all, the evidence supports the idea that this is a dike of dacite with a north-south direction with apparently greater width north of the Laguna, which is probably the source of a portion of the dacite intrusion. If this dike is as suggested, and wider to the north of the

Laguna, it will be expected that the fault in breaking its way upward through this dacite will show greater irregularity than would otherwise be expected. Generalized section II illustrates this situation and practically represents the conditions existing as far north as the end of the dacite area, in the vicinity of the Berkeley property.

Mineralization

The various orebodies of the Goldfield Consolidated and the Florence mines are directly connected with this Columbia Mountain fault zone; all of them being either in the zone itself or in the irregular fractures extending from it upward. It seems reasonable, therefore, to conclude that this fault has been the connecting channel to the deep seated source of mineralization, and the path for mineralizing solutions.

What is believed to be primary ore has already been found on the 1300-ft. level of the Grizzly Bear in this fault zone. The natural tendency, in a fault as flat as this, is a closing of the fracture by compression, and the consequent difficulty of the circulating waters to maintain their open channels. This accounts for the larger size of the orebodies in the upper and more nearly vertical and irregular connecting fissures than in the main channel below. It is reasonable to expect that the deposition of mineral in the channel itself as depth is increased will be of less thickness, while in the steeper intersecting veins it will not be so much restricted.

Relation of Mineralization to Faults

The mineralization appears to depend entirely upon the system of fissuring, and there appears to be no essential relation between the ore deposits and the different kinds of eruptive rock in which they exist, and references to the different kinds of rock are made here for the purpose of exhibiting the system of faulting and fissuring. There has been some cross-faulting both prior to and after the deposition of the ore, which has not been mentioned here, and has to some extent modified the uniformity of the fault and connecting fissures, but has not substantially altered the general scheme.

To the north of the Berkeley property the conditions are somewhat simplified by the absence of the dacite intrusion. This situation is represented in generalized section III. Some ore has been found in the fault zone at the Conqueror mine, which leads to the inference that there are connections along the zone to the source of the mineral solutions, through which they have penetrated this far to the north. There may be a branch from this fault or a connecting fissure extending farther to the west, which has mineralized the area including the Sandstorm and Kendall properties. This system of connected faults and branching fractures is by no means unusual and many notable similar instances are found in mining camps throughout the country. It is not intended here to convey the idea that there are not other sources of mineralization for other portions of this district, or that there may not be many more connecting mineralized fractures extending from this system, which as yet remain undiscovered and which the future will reveal.

The Basic-Lined Converter

By E. P. MATHEWSON

*In a discussion of a paper on 'The Basic Process as Applied to Copper Smelting,' by Percy C. Gilchrist, read before the Society of Chemical Industry, London, January 5, 1891,[†] W. C. Roberts-Austen asked Mr. Gilchrist whether he thought that the substitution of a basic lining for acid lining in the Manhès process would afford anything like the service which it had been shown to render in the metallurgy of iron.

Claude Vautin stated that he had experimented for over two years with basic linings for bessemer converters for copper mattes at Cobar, but had given up the attempt on the score of cost. Mr. Gilchrist in his reply stated that he did not believe in applying any system of bessemerizing to copper.

About the time of the presentation of the paper mentioned, Herman Keller, superintendent of the Parrott smelter, in Butte, was experimenting on a large scale with converters lined with magnesite brick. He gave up the idea on account of the cost of linings and because no particular advantage was observed. My belief is that his tuyeres and converters were too small.

Experiments at the Great Falls Plant

A short time afterward, similar experiments were tried at the Great Falls plant of the Boston & Montana company, and at the Old Works of the Anaconda Copper Mining Co. at Anaconda. These were abandoned on the score of cost and the lack of advantages. The same cause of failure, in my opinion, holds here. The Anaconda Copper Mining Co., however, adopted the magnesite brick lining for its tilting casting machines.

E. A. C. Smith, while temporarily in charge of these casting machines, tried the experiment of blowing the copper in the casting machines, but the return of the head of the department put a stop to the experiment, and Mr. Smith put the idea away until a more favorable opportunity presented itself.

About 1903, Baggalley began his experiments of smelting ore in a basic-lined converter at Butte, Montana, at the Pittsmont smelter. He was followed by Knudsen at the Sulitjelma plant in Norway, in 1907. About the year 1905 similar experiments were tried at several smelters, notably the plant of the United States Smelting Co. at Midvale, Utah. Mr. Smith, who was then with the Baltimore Copper Co., found his opportunity to experiment, and his superintendent and manager, Mr. Pierce, gave him all the help in his power, the result being the construction at Baltimore of a basic-lined converter for leady copper mattes, along the lines of the old tilting anode furnaces of Anaconda. The experiment gave promising results, so that the American Smelting & Refining Co. took up the process and introduced it with success on leady copper mattes at its lead re-

fineries at Perth Amboy and Omaha. Then Smith and Pierce persuaded the company to try it on straight copper mattes at the Garfield, Utah, plant.

In the meantime the Anaconda Copper Mining Co., at the Washoe Reduction Works, Anaconda, lined a shell of the standard trough pattern with magnesite brick. The results were excellent, so they gradually replaced all the acid lining with magnesite brick. At Great Falls the same Company's experts developed a large converter along the lines of the upright shell, and, as this type is easier to build and keep in repair, it has become the standard during the past year. Practically all the bessemerizing of copper mattes in the United States is now done in basic-lined converters. The main points to be observed for successful operation of the basic linings are: not to exceed a temperature of 2100°F.; not to have tuyeres smaller than 1¼ in. (1½ in. is the preferred size); to drive in punch rods the full size of the tuyere opening, immediately after pouring the copper; to maintain in the converter as large a mass of matte and slag as possible to prevent sudden changes in temperature and overheating of the lining; to employ slag containing preferably about 25% of silica.

A test was made with a view to finding out whether the cutting action of converter slag on a magnesia brick lining bore any relation to the silica content of the slag. Thirteen slags were selected from the daily samples sent to the laboratory. These varied in silica from 22.4 to 37.8%, and were carefully analyzed for MgO. The results showed no relation between silica and magnesia content.

To Smith and Pierce belongs the credit of taking a long-discarded idea and developing it into a successful process. The great advantages of the process are: decreased cost of lining; the ability to use large units in converting, with consequent economies in labor, power, and repairs; neatness and cleanliness of plant, abolishing the danger, from dust, to the health of the lining crew.

Improvements at the Old Dominion Mine, Arizona

The steel erecting gang is working on the new sampling mill, adjacent to the big concrete concentrating ore-bins. The main work is almost complete, but some riveting remains to be done. The steel work on the crusher plant has been delayed because of the late arrival of the steel building columns, but these are now at hand and the contractors will go ahead with the erection of the building immediately. All the steel work is being done by the Darbyshire-Harvie Iron & Machine Co., of El Paso. All necessary excavation work in connection with the new concentrator has been completed, and forms are now being put in place to receive the concrete. The foundations for the rolls are already in place. The steel work on the new concentrator will not be started before the crusher plant, sampling mill, and various conveyors are all complete. Plans are being made to double the present capacity of the custom ore-bins, which are above the A shaft, to give more storage room at that point. The

*Abstract from advance copy of paper to be presented at the Butte meeting of the American Institute of Mining Engineers.

[†]*Journal of the Society of Chemical Industry*, Vol. X, No. 1, pp. 4 to 16 (Jan. 31, 1891).

timbering and lining of the pockets at the 1200 and 800 ft. levels has been completed, and a pocket is being cut for the concentrating and smelting ore on the 1600-ft. level, the lowest level of the shaft at the present time. Several changes are being made in various stations near the shaft in connection with the new skip arrangements, and the tracks will be changed later. Ore production and development in the mine continues about normal. The sinking of the K shaft for a sump, below the 1400-ft. level, is finished, and in a few days all timbering will be in place and the shaft will be ready for hoisting ore at any time. It is expected that the raise from the 1200-ft. level of the Old Dominion to connect with the present bottom of the Gray shaft will hole through about July 5, and the shaft will then be timbered with sets down to the 1200-ft. level. A new slime pond has just been completed near Pinal creek on the old Hamm ground, and will be used for settling slime from the concentrator. There are no changes or improvements of note around the smelter.

Portable Electric Mine Lamps

By H. H. CLARK

*Portable electric lamps should first of all be safe; that is, they should not be capable of igniting gas, and should not be so poorly constructed that a man will be left in darkness due to failure of any part of the lamp equipment. The lamp should give the proper amount of light for from 10 to 12 hours on one charge of battery. The lamp equipment should be as light as possible, so that the burden of carrying it and working with it may be reduced to a minimum. Some of these qualities are more or less apparent after a brief examination. There are other qualities that are not so easily determined, and I will mention just a few of them:

A most important factor in the usefulness of portable electric lamps is the cost of repairs and upkeep; another is the trouble that is experienced from interruptions of service due to equipments getting out of order. The principal item of upkeep is the expense of replacing the lamp bulbs that have burned out. The life of the lamp is, therefore, an important consideration. The manufacture of miniature lamp bulbs does not seem to be very thoroughly standardized in this country. The lamp bulbs that the Bureau has examined have varied a great deal in their characteristics. These bulbs vary in price from 17c. to over 40c., and it may be supposed that the higher-priced lamps have a longer life, but I cannot give any definite information as to that, although tests are now under way to determine this fact. The candle-power that these bulbs will give is not a fixed quantity, as it varies with the voltage at which the lamps are burned. If a lamp, designed for two-volt service, is burned at less than two volts, it gives less candle-power and has a longer life. If, on the other hand, it is burned at $2\frac{1}{4}$ volts, its candle-power would be increased and its life proportionately shortened. It is not

always a good sign to see a lamp bulb glowing with extreme brilliancy, because it may mean that the lamp is being used at too high a voltage and may last but a few hours at the most.

Battery Plates

Another item in the cost of upkeep is the decomposition of the battery plates or elements. This is most noticeable in storage batteries having lead elements. The natural depreciation of the plates is hastened by overcharging, overdischarging, or charging at too high a current. Another trouble that is experienced with the acid batteries is the destruction of the contacts by the acid from the battery. Even in non-spillable batteries and batteries using gelatin electrolytes, a certain amount of acid often gets upon the contacts, and rapidly corrodes and destroys them. A good deal of this trouble may be eliminated by properly designing the battery, but it may be prevented even more completely by exercising care to keep the batteries clean and the terminals occasionally wiped off with vaseline or some similar substance. Storage batteries that make use of other electrodes than lead and other electrolytes than sulphuric acid are not materially injured by overcharging or overdischarging, and do not have trouble with the corrosion of the contacts. All the batteries that the Bureau has tested, however, have shown a more rapidly decreasing voltage curve than the lead batteries, which means that the candle-power of the lamp when the battery is first charged will be a good deal higher than it will be near the end of the discharge.

Candle-power of Lamps

Another point that I wish to speak of is the matter of candle-power ratings of portable lamps. Up to the present time, so far as I know, no standard candle-power rating of portable electric lamps has been adopted. I want to call your attention to the different meanings that may be given to the word 'candle-power' as applied to portable electric lamps. If a man speaks of his lamp as having five candle-power, he may mean the candle-power of the lamp bulb used in connection with its reflector. In either case he may refer to the candle-power measured at one point or the average of several points. The true candle-power of the lamp is, of course, the average candle-power that it gives over its illuminating range. Some lamps if measured from a point directly in front of their reflectors, will show from 5 to 10 times the candle-power that they would have if their candle-power were measured from a point 30° on either side. An effect of this sort is, of course, to be expected, but the statement as to how the candle-power is measured should always be made, because two lamps that really give the same amount of light have widely different candle-powers when measured 'head-on.'

As an illustration: Two lamps give the same amount of light, but the 'head-on' candle-power of one is more than twelve times that of the other, and the average candle-power is nearly seven times that of the other.

*Address delivered before the Coal Mining Institute of America on June 18, 1913.

A growth of scrub willow in Alaska is usually an indication that the ground below is not frozen.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

The Psychology of Zinc

The Editor:

Sir—There was produced in the United States in 1912 more than 320,000 tons of metallic zinc, worth more than \$45,000,000. To produce this amount of metal, over 100,000 little fireclay pots were constantly in use night and day. The average life of these pots is only a few weeks, and when one is broken it must be replaced. As a result, the total number consumed was between one and two millions. For each of these pots in use, a smaller bottle-like vessel of fireclay is required; the life of these smaller vessels is even shorter. The service required of these petty utensils is strenuous, and the handling they receive is necessarily rough, consequently only the best obtainable clays can be used in their construction, and great technical skill is required to make them. A rigorous supervision must be exercised over every stage of their long evolution. They must be dried out gradually during several months, and properly heated afterward, before they can go into a hot furnace to replace those which are broken. They must be handled like crockery, and yet be charged and emptied once every twenty-four hours with heavy iron tools which only a strong man can manipulate. It is a triumph of manual training which makes it possible to use them at all. Yet it is assumed that they are indispensable with a resignation which may be truly Christian or merely fatalistic.

The success in finding suitable clay, the care taken in preparing it, and all the little refinements in manipulation practised, and the slight changes in size and shape of the vessels adopted from time to time for economy, show to what extent the art of making them has been perfected. Most of the ore from which this zinc is smelted is mechanically concentrated out of material which contains less than 4% of zinc as it goes to the mill. From this material a rich concentrate containing between 50 and 60% of zinc must be made before the smelters will look at it. The percentage loss in this mechanical concentration is very high. These two facts, the successful use of fragile vessels on a large scale, and the successful concentrating of lean ores, are taken as evidence of an advanced stage of development in the art of zinc smelting. This 55% concentrate is, however, not yet ready to be put into those precious vessels; it must be roasted to get rid of its sulphur. An incomplete roast will not suffice as in many other branches of metallurgy; practically all of the sulphur must be eliminated. Here comes in another evidence of the success achieved in zinc smelting, for the sulphur is reduced to less than 1%, and this result is announced with pride. Still another evidence of acquired skill is to be found in the drawing and casting of the smelted metal, for each of the little bottles (condensers) attached

to the pots (retorts) must be emptied from three to five times a day by scraping its contents into a ladle which holds perhaps twenty pounds. The metal in these ladles, after it is skimmed, is poured into a larger ladle, from which it is poured into the molds, after proper cooling. The skill shown in these operations is admirable.

There is another side to the story outlined above. It is a fact that enormous deposits of mineral containing from 6 to 20% of zinc are easily accessible, some of them opened by shafts and drifts, but they are not available because they are not amenable to the high concentration possible on some leaner ores, or because they cannot be roasted down to less than 1% of sulphur. These masses of rich raw material are a nuisance where they are found, in working mines for other metals and they are doomed to be irrevocably lost, when these mines are shut down, unless happily rediscovered by posterity and utilized by a new order of zinc smelters.

It might be supposed from the foregoing outline that zinc is connected with some particularly troublesome associates. This is not the case. The elements found with it are those with which every metallurgist is familiar, and has to do with every day. There is little foundation for the suppositions that zinc has properties which make its separation from other metals difficult, or that there is some great difficulty in smelting.

Zinc has indeed two properties which impose special conditions on its metallurgy: the temperature at which it is reduced by carbon is above its boiling point, and consequently as reduced it exists as a gas, in which state it is easily oxidized. Both of these properties belong also to mercury, which is smelted from much leaner ores. On the other hand, zinc has properties which make its smelting very simple. Isolated by volatilization, it is easily separated from its metallic and earthy associates, and it is in fact the only metal which I know of, which is commonly used in the arts just as it comes from the smelting furnace. The temperature needed to reduce it is moderate, that is, about the same as in the simplest lead-smelting process, much less than is required to smelt iron, copper, nickel, or aluminum, or than is constantly employed in working up iron and steel products.

Smelters in other branches of metallurgy show a willingness to discard furnaces and machinery known to be obsolete. They experiment to find something better. They are willing to build furnaces which they know are not perfect, but will have to be discarded or improved later to get the best results or to meet changed conditions. Change does not repel them. But zinc smelters cling to their precious pottery, to their petty charges, and skilled practices of a traditionary art, to their costly but perfected roastings, and they shudder at any suggestion of change. It is said zinc smelting was invented in China several hundred years ago. It has been also said that the zinc industry is a backward one; it is rather a perfected one. I am inclined to think that all of its skill and most of its technical knowledge is to be found with its manual workers. At a consultation held between its family physicians

and one or two outside specialists called in for the sake of appearances, mutterings very much as follows would be heard from the several participants: "One of arrested development—congenitally defective—unsanitary conditions—vocational disease—inherited—incurable—hopeless—will live indefinitely—no suffering—happy as a child—inherited wealth—sad case." The consultation will be secret, for everything connected with zinc is done with decorous secrecy. It will be painstaking and detailed, for everything connected with zinc is in perfect detail, and everything is done with pains.

I think there are no zinc smelters on the Pacific coast of this continent, and no friends of the family whose feelings might be hurt by the indiscreet admissions I am making to the *Press*, and China is a long way off from there, whether one goes east or one goes west, and news travels slowly in the zinc world. These are feelings of traditional reverence which everyone should avoid shocking, intentionally or otherwise. I don't want to be thought uncharitable or unkind. There are cases which are sadder than death; they should be spoken of in private, and with hushed voices. I hope my voice is not too loud. Sorrow for the stricken must find a place in every bosom capable of human feeling, but the inevitable must be faced somehow. *Requiescat in pace.*

F. L. CLERC.

Estes Park, Colorado, June 9.

[The statement that zinc metallurgy is backward is frequently made. It is true that the recovery is less than in treatment of copper, gold, and silver, but we believe that this results from real difficulties and is not wholly a matter of tradition. Certainly, the metallurgists that we know, who are working with zinc, are as capable and energetic as any. We hope to see treatment improved. In the meantime our correspondent's semi-serious pen picture will serve as a protest and stimulant.—EDITOR.]

Oil-Burning in Furnaces

The Editor:

Sir—In my letter on 'Blast-Furnace Smelting with Crude Oil,' published in your issue of February 8 last, I endeavored to emphasize the necessity of thoroughly consuming the oil before the entrance of the mixture of hot gases into the furnace. That such emphasis was needed is shown in a variety of ways. I have heard subsequently of two different attempts to utilize oil as fuel in cupola smelting, which came to naught, apparently by a neglect of this principle. Observation of oil-burning boiler furnaces, so common now, will suffice to show the necessity of a thorough preliminary combustion. The conditions essential to complete combustion—which, by the way, never takes place under steam boilers—are these: There must be enough, but not too much air; the space within which the combustion takes place must remain at the highest possible temperature; the space must be ample; and its form must be such that there be no interference with or between the gaseous currents. The ideal form would be tubular. The best construction would be cylindrical, being composed, let us say, of a sheet-iron

tube lined with firebrick of good thickness, and placed horizontally. The diameter should conform to the amount of oil to be consumed, and its length should be such that the gases would be thoroughly burned, and that no smoke, the sign of faulty combustion, should issue from the far end. The temperature at the front (where the air and oil enter) will necessarily be less than at the back, but should be kept as high as possible, by cutting off the direct radiation of heat outwardly by means of baffle-plates. It is contrary to common sense to permit of openings at any point wherein the interior can be seen. The fire-chamber is, of course, connected to the furnace proper, and when thus connected to a blast-furnace would constitute a tuyere. Several of them would be provided for each furnace, spaced regularly about its periphery, and pointing radially inward, or having some inclination downward, according to the fancy of the designer. They must be contracted at the inner end, to increase the velocity of the entering gases and assume the customary effect.

The application of oil-burning to the steam boiler is not scientifically made. The old-fashioned coal or wood-burning firebox is retained and made to do a duty to which it is not well adapted. The interior form of the fire-box is about the worst that could well be devised. Its faults for oil-burning are, first, its many rectangles, which produce conflicting gas currents and prevent the proper mixing which is essential to perfect combustion. Then the large useless space at the front, which cannot be kept hot; but chiefly the presence of the immense bulging boiler immediately over the fire at its incipency, which effectually keeps down the temperature, which, instead of reaching 3000° or more, as it should, can barely surpass the red heat. I do not mean that all the space is at this low temperature, but that it does not surpass the red heat as an average.

When a liquid or gaseous hydrocarbon burns, the tendency is for the hydrogen to be consumed first, as the carbon, requiring a higher temperature, may escape combustion in part, passing off in solid particles and making a black smoke. A cold object introduced into the path of the burning gases abstracts heat and produces the smoky effect. The bulky boiler, relatively cool, is responsible for the great volume of smoke and soot which often defiles the atmosphere in the neighborhood of steam plants. The remedy is obvious: it is to burn the fuel out of contact with the boiler, and to heat the latter by contact with the fully burned and very hot gases. Smoke is so unnecessary that it is quite a wonder that legislative interference has not been invoked effectively; a proper 'blue-sky' law should be placed on our statute books.

It is in reverberatory smelting that oil-burning has reached its ideal phase. In that furnace the whole interior forms practically a great combustion chamber, kept at a high temperature throughout its entire length (exceeding in some cases 100 ft.), into one end of which the air and atomized oil are introduced, while the fully oxidized gases are with-

drawn from the other. Being surrounded by brick-work, cunningly arranged to prevent the escape of heat by radiation and conduction, the whole interior remains at a dazzling heat, the conditions being perfect for the development of the flame and the complete combustion of the fuel. This condition of affairs should be imitated so far as practicable in the other applications of petroleum as fuel, even if it involved the construction of special combustion chambers. Such constructions are in the way of being realized. Several manufacturers of oil-burning boilers manifest, in their catalogues at least, a tendency to prolong their combustion chambers outwardly, or by extending an arch over the internal combustion space, which comes to the same end, to give the fuel a chance to develop its flame unhampered by the presence of the cold boiler surface.

HERBERT LANG.

Oakland, California, June 6.

The Mother Lode of California

The Editor:

Sir—In your issue of June 21 appears an article on 'The Mother Lode of California,' by J. H. G. Wolf. I consider this an ably written article on the Mother Lode, especially in reference to Amador county, and in fact all other districts mentioned in this article except that part of Calaveras county between the Mokelumne river and the Utica mine at Angels Camp, a distance of about 26 miles on the Central belt of the Mother Lode.

Mr. Wolf intimates that the productiveness of the Lode is lost. He omitted to mention the Gwin mine, about $1\frac{1}{2}$ miles south of the Hardenburg, which property has been a producer of several million dollars and has been worked to the 2600-ft. level. Other mines south along the Lode are, The Hamby and Quaker City, that has produced gold as far as it has been developed; near San Andreas, the Gold Hill, Lookout, and Gottschalk mines have been prospected and from all indications are the making of paying mines, and in all probability as good payers as the Kennedy or any of the Amador properties. They are not unlike the mines of Amador county.

South from San Andreas, and north of Altaville, are other good prospects. They are, the Ford, Fellowcraft, Illinois, Rathgib, Thorpe, and others that have been developed for several hundred feet with good results. The only trouble on this part of the central Mother Lode is the want of capital to develop the mines to the same extent as in Amador county. The Lode did not break its neck at the Mokelumne river. In time it will be found that the Lode south of the Mokelumne river will prove equally as productive as in Amador county or at Angels Camp.

W. T. ROBINSON.

Mokelumne Hill, California, June 25.

The number of productive mines in New Mexico in 1912 was 145, of which 26 were placers, against 105 in 1911, of which 20 were placers, according to the U. S. Geological Survey. The average total recoverable value per ton of ore produced decreased

from \$11.54 in 1911 to \$6.29 in 1912, owing to the large tonnage of low-grade copper ore handled by the Chino Copper Co. A total of 1,352,286 short tons of ore from New Mexico was sold or treated in 1912, an increase over 1911 of 1,119,587 tons. Of this total, 106,198 tons went to amalgamating and cyaniding mills, 1,142,002 tons went to mills for concentrating only, and 104,086 tons went crude to smelters.

Analysis of Black Powder and Dynamite

Bulletin No. 51, recently issued by the United States Bureau of Mines, outlines the methods of analysis that are used by the Bureau of Mines in the examination of certain classes of explosives. The present form of most of these methods has been worked out in the Bureau's explosives laboratory. The methods employed by C. E. Munroe have been taken as a basis, and were elaborated to meet the demands incident to the treatment of complicated mixtures and to the development of the explosives art. This bulletin presents the methods of analysis of 'ordinary' dynamite, and the ammonia, gelatin, low-freezing, and granular dynamites, and the common grades of black gunpowder and black blasting powder. The bulletin is published by the Bureau for the information of all persons interested in explosives and their safe and efficient use in mining work. It may be noted that the standard dynamite used at the Pittsburgh testing station is a good example of the 'ordinary' dynamite known in this country. This testing station dynamite has the following composition:

COMPOSITION OF PITTSBURGH TESTING STATION DYNAMITE

	Per cent.
Nitroglycerin	40
Sodium nitrate	44
Wood pulp	15
Calcium carbonate	1

As most permissible explosives contain only the constituents found generally in the various types of ordinary dynamite, the chemist will usually find it possible to analyze such explosives either wholly or partly by following the general methods of analysis here given for the type of explosive that seems most closely related to the one under examination. The methods of extraction with ether, with water, etc., outlined in the bulletin are general methods which are applied with equal success to all classes of explosives, and therefore by the use of these general methods, following a thorough qualitative examination, little difficulty should be met except with those classes of permissible explosives that contain large amounts of salts holding water of crystallization, such as alum and magnesium sulphate, or those containing an unusual number of uncommon constituents. Even with such explosives, however, if the information desired is principally in regard to the percentages of explosive ingredients (nitroglycerin, ammonium, nitrate, etc.), the methods outlined in this bulletin may be satisfactorily followed.

Corporation taxes during the year ended June 30, 1913, yielded the United States government \$34,948,870.

Special Correspondence

BOISE, IDAHO

THE PEARL DISTRICT.—CHECKMATE MINE.—LINCOLN.—BLACK PEARL.—WHITMAN.—MISTAKES IN EARLY WORK.—CYANIDATION NEEDED.

In many districts the refractory nature of the ore has been the serious drawback to the successful development of mines. In some respects this is true of the Pearl district, though the principal drawback appears to have been lack of method in determining the true nature of the ore and its adaptability to certain methods of treatment, previous to the erection of milling plants. The valuable minerals consist of gold and silver, intimately associated with pyrite, blende, galena, and small amounts of stibnite and chalcopryrite. In many of the veins the sulphides occur at the surface or within a few feet of it. Some gold occurs 'free', but most of it is in the sulphides in the form of thin flakes deposited along the cleavage-planes of the mineral. The gangue is silicious, carrying a small amount of lime in the oxidized zone and some calcite both in and

MAP OF IDAHO.

below this zone. In general, the ore from all the properties is similar in character, at depth, the principal difference being in the varying quantities of blende and galena associated with the pyrite. The arsenical content varies somewhat in the different mines, and even in different parts of the same mine; this factor appears to have had an influence on the deposition of gold. In the Whitman mine the arsenical ore carries the highest gold and silver content, while in the Checkmate mine the reverse appears to be true. The reason for this apparent inconsistency has never been determined.

During the early period of mining, the Checkmate company erected a mill, including two 5-stamp batteries, vanners, and canvas tables, and this mill was operated almost continuously for more than five years. The orebody developed consisted of three shoots of fair length and width, which came together at depth, forming one shoot nearly 600 ft. long. A portion of this orebody was of shipping grade, the value never falling below \$75 and often going as high as \$150 per ton. Within the orebody the gold and silver content was consistent and quite uniform, a fact which distinguishes the Checkmate from

other properties in the same mineralized area. A fact also worthy of note is the occurrence of galena in appreciable quantities. Invariably, where the amount of galena is high, the gold content is good, and this is true of all the mines. The ore sent to the mill yielded well to amalgamation and produced a good grade of concentrate. Repeated checks on heads, tailing, and the actual recovery in amalgam and concentrate showed an extraction of only 62%. Undoubtedly a large part of the loss was due to sliming the lead sulphide. The mine was developed to the 500-ft. level, but with the destruction of the mill by fire several years ago, operations ceased. Later, lessees worked the upper levels at a profit. The property is credited with a production of between \$500,000 and \$750,000.

The Lincoln mine has been opened by shaft to a depth of 400 ft. The vein varies in width from 2 to 30 ft., and at the widest point was heavily mineralized. This stope was opened from the inclined shaft before the vertical shaft was sunk, and some ore was taken out. This body of ore was lost, however, because proper precautions were not taken in mining. The full width of the vein was mined and a kind of square-set timbering was used to hold the exceedingly heavy hanging wall. No filling was used. The vein-matter was soft and a six-foot auger hole could easily be made. The men were instructed to be liberal in the use of powder, and they were. The holes were charged to the collar and when blasted not only broke the ore, but the timbers also suffered severely, and as a result the hanging wall fell, taking everything with it. The swelling ground in the drifts caused trouble, and 1200 ft. of the second level, from the incline shaft through which the first work was done, was lost and never recovered.

The treatment of the Lincoln ore was similar to that of the Checkmate, in that amalgamation and concentration were employed. The equipment consisted of a crusher, rolls, Chilean mill, plate, and Wilfley tables. Everything went through the Chilean mill, and as the mine, at times, was in condition to produce a good tonnage of ore, the Chilean was often crowded beyond capacity. Amalgamation followed immediately after grinding, and generally the stream of pulp over the plate was so thick and flowing at such speed that amalgamation was almost useless. An electro-amalgamation device was tried later, but the conditions necessary to good practice were ignored. Concentration on the tables was somewhat more successful than amalgamation, this being due to the fact that the Wilfley table is one of the most easily handled and understood of all concentrating devices. Some of the mill-ore was rich in free gold and at such times there could be observed a streak of the yellow metal traveling down the table above the pyrite. This helped to raise the grade of concentrate, but it certainly did not raise the efficiency in milling. The record of production is not complete, but the books show nearly \$240,000 in shipments, of which \$50,000 was bullion to the Boise assay office. Considering all the impediments to good work under which the mine and mill labored, the extraction would not exceed 50 per cent.

The Black Pearl mine is also developed by shaft to a depth of 400 ft., and is equipped with a complete mill, consisting of a battery of eight 1250-lb. Nissen stamps, Dorr classifier, Abbé tube-mill, Hendryx agitator, Kelly filter-press, Card concentrators, steam plant for heating solution, zinc precipitation, filter, and zinc press, melting furnace, and the usual tanks. From the standpoint of mechanical efficiency, the mill was up to date, but metallurgical troubles were experienced. Before these were adjusted, the financial resources had been exhausted, and the property was closed. The final plant was not finished until after expensive and time-consuming experiments had been made on other methods of treatment, the first of which was the percolation process. Percolation could not possibly be successful with the heavy sulphide ore, owing to the nature of occurrence of the gold and the tendency of the pulp to pack when charged into tanks.

The Whitman mine was being developed during the time that the other properties mentioned were producing, and should have profited by the experience of the pioneers in

milling. The mine is opened by an adit at a depth of nearly 200 ft., and for a distance of 1400 ft. on the vein. A Hathaway type of mill was built and operated with more or less regularity for two years. The capacity was limited, and the mine production had to be cut to conform with mill capacity. Early in 1910 it was decided to increase the milling capacity, and the Hathaway mill was consigned to the dump. Rolls, jigs, trommels, tables, and vanners were installed in the former mill building, which had been remodeled and enlarged. The equipment was placed in position, and in July milling operations were commenced. No one understood jigs, this being the first installation in the district, but finally, after considerable delay, a millman from the Coeur d'Alene district was secured to start the plant. The millwright had piped the jig water into the air vents of the plungers, and had merely placed the screens on the frame without even one little nail to hold down the cloth. The re-grinding rolls were directly under the trommels and some 12 ft. below, and as a result the product dropped, without a break, to the rolls. The feed-spout from the feeder to the coarse-grinding rolls made a right-angle turn and was flat enough to keep the millman continually poking the ore past the turn. The new millman found his suggestions for a few improvements, which would make the work easier and increase the efficiency, taken with little grace. Also, he found it difficult to satisfactorily explain just why clean concentrate could not be made on the third screen and through the third hutch—the two jigs were three-compartment. The middling was not returned for re-grinding, but was wheeled back and shoveled into the boot of the elevator and returned to the system. More could be given, but these points are enough to illustrate the lack of system in the matter of design and erection, and particularly in the knowledge of the ore and its concentration.

The mill ran several months under very unsatisfactory conditions and milled a fair tonnage. The grade of concentrate was lowered beyond a profitable point by allowing the pyritized wall-rock to go in with the regular ore. In places the hanging wall was well mineralized, but the pyrite contained low gold and silver content. An assayer was employed, but his principal duties consisted in running the crusher, as assays were made about once, and sometimes twice a week. Mine assays were few and far between, and consequently of little value in a vein where the difference between profitable and unprofitable ore could be determined in no other way. A change in management the latter part of the year was followed by a general change in the operating force, as well as in policy, all of which resulted in benefit to the owners.

In 1911 the mistake of attempting cyanidation in the Black Pearl mill, leased for the purpose, cost the owners about \$10,000, and resulted in shutting down the property and settling with the crew on a basis of 75% of their wages. The data, on which the cyanide plant was started, consisted of several laboratory experiments, and nothing more. In this work the ore was concentrated in the Whitman mill and the concentrate hauled by wagon to the Black Pearl mill and dumped into a bin erected for the purpose. The equipment at the Black Pearl mill included a tube-mill, agitator, tanks, and zinc-boxes. The mill had been idle more than three years and was in bad condition, so that considerable loss of gold solution as well as barren solution was unavoidable at the beginning. The first mill-runs did not, of course, check with laboratory work, so the entire plant was turned into an experimental mill. To conduct such an experiment and at the same time keep 35 or more men on the payroll is exceedingly costly. The owners had not objected to paying for nearly 5000 ft. of development and the erection of the two mills, but this premature attempt at cyanidation was too much.

While this did not result in commercial success, it was of some value in indicating what could be expected in the matter of treatment. A total of 598 tons of concentrate was treated, the average value of which was \$17 per ton. Close concentration was not attempted in the Whitman mill, and for this reason the percentage of silica reduced the value of the material treated. The calculated

extraction was 76%, amounting to \$7727, and the actual recovery was \$6174, which amounts agree fairly well, considering the loss from leakage and other causes. Precipitation with zinc shavings was not very efficient, being only 89.56%. This low extraction was due, in part, to the use of old factory-made shavings and to lack of definite knowledge in the use of lead acetate. The cyanide consumption averaged 4 lb. per ton of ore, and the lime 8 lb. The record of zinc and lead acetate consumption is not complete, nor were other costs kept in shape for tabulation. The entire cost, including all alterations, repairs, supplies, labor, power, etc., amounted to \$6.27 per ton. There is no question but that a good plant in charge of a competent metallurgist would reduce this cost to below \$5 per ton, and at the same time increase the extraction.

The general conclusion to be drawn from observing conditions in this district is the fact that all companies, aside from the Checkmate, erected mills from hurriedly prepared plans, seemingly under the impression that any mill would answer the purpose. This error seems to be an inherent quality in the conducting of operations among smaller mining companies. The building of a mill marks a critical point in the history of any mine. If the mine has been developed to the producing stage and the mill is not economically adapted to the ore, the final outcome is much the same as if a mill had been built with the expectation of later developing ore in the mine. The mines here have ore, but the general run of ore is not high enough in gold and silver to pay interest on capital invested in equipment necessary for concentration and shipment to smelters. Cyanidation is the logical and inevitable solution of this district's problem, and when the demand for the precious metals becomes more insistent, this district will be a producer.

HIGHLAND, WISCONSIN

ZINC-LEAD PRODUCTION DURING JUNE.—ZINC PRICES.—IRON PYRITE PRODUCTION.—CARBONATE OF ZINC ORES AND THE MINERAL POINT ZINC CO.—ZINC ORE OPENED AT THE CRAWHALL MINE.—PRINCIPAL PRODUCING MINES.—PROSPECTS OF THE DISTRICTS.

June reports at hand for the entire Wisconsin zinc-lead field show shipments to local ore-separating plants and smelters direct consisting of 288 cars of zinc ore, equal to 20,850,000 lb. Of this production, the Mineral Point Zinc Co. secured by purchase and production under company management, 4140 tons; Grasselli Chemical Co., of Cleveland, 2625 tons; National Separating Co., owned and operated by the Vinegar Hill Zinc Co., 990 tons; Illinois Zinc Co., Peru, Illinois, 675 tons; Matthleson & Hegeler Zinc Co., 580 tons; Empire roasting plant at Platteville, 700 tons; Linden Zinc Separating Co., 450 tons; American Zinc Co., of Hillsboro, Illinois (new smelter), 245 tons; and the Joplin Separating Co., Galena, Illinois, 45 tons. The latter was purchased during the last week of the month and shows that the plant had resumed operation after a shut-down of 60 days.

The gross production of zinc from mines during the month totaled 18,000,000 lb., and net to smelters of 13,345,000 lb. Prices averaged from \$40 to \$43.50 per ton, on a basis of 60% zinc content. The wide latitude between high-grade and low-grade zinc ore in this field makes the intervening markets interesting. The average 30% grades of zinc ore brought \$16.50 per ton; 40%, \$20 to \$24 per ton; and 50%, \$26 to \$30 per ton.

Iron pyrite fell off considerably as compared with the output for May. The Wilkinson mine, at Benton, shipped 1,486,600 lb. to the General Chemical Co., Hegewisch, Illinois; to Grasselli Chemical Co., East Chicago, Indiana, 1,600,000 lb.; the Linden shipped 500,000 lb., and the National Separating Co. delivered 465,000 lb., a total of nearly 4,000,000 pounds.

Lead ore deliveries were made mostly to the Federal Lead Co., N. H. Snow, buyer, securing six out of seven cars sold during the month. The price remained steady at \$52 per ton on a basis of 80% metallic lead. Considerable

lead ore and zinc ore are held in reserve at several points in the field.

Carbonate of zinc ore, locally termed 'dry-bone,' is being delivered at a good rate. The Mineral Point Zinc Co. paid as high as \$22 per ton during the last two weeks of the month, a price never before reached in this district. This Company consumes about 200 tons of 'oxide-producing' ores each 24 hours, and is constantly in the market for this material. The carbonate of zinc ores are rich in oxides, and for this reason the Eastern corporation has practically bought up everything in the two northern 'camps,' Centerville and Highland. The Company now owns five mining plants fully equipped and will secure two more. In addition, fee to more than 2000 acres of land has been purchased outright, and all of this is to be prospected and mined. Officials from the head office of the Company, in New York, personally inspected the new holdings in this

both operated steadily, but stored their product in bins holding for better prices. At Cuba, the Burr mine produced 4 cars, and the National Separating Co. shipped 9 cars of roasted ores. At Benton, the Frontier, Fox, Fields, Indian Mound, Rowley, and Temple mines made good outputs. Shullsburg witnessed a heavy production in the Wnskill, Rodhams, and Milwaukee-Shullsburg mines. Hazel Green reported its usual fine showing out of the Kennedy and the Cleveland and Scrabble Creek mines. Galena reported heavy deliveries of ore from the Federal, North-western, Betsy, Vinegar Hill, and Indianapolis mines. Highland reported light shipments of carbonate of zinc ore, with only 4 cars. A good deal of ore is ready for delivery here and at Centerville. No building is being done on the field, and drilling has lessened considerably since lower prices for zinc ore went into effect. Any improvement in the ore market will be reflected by an almost immediate increase in production.

NEW YORK

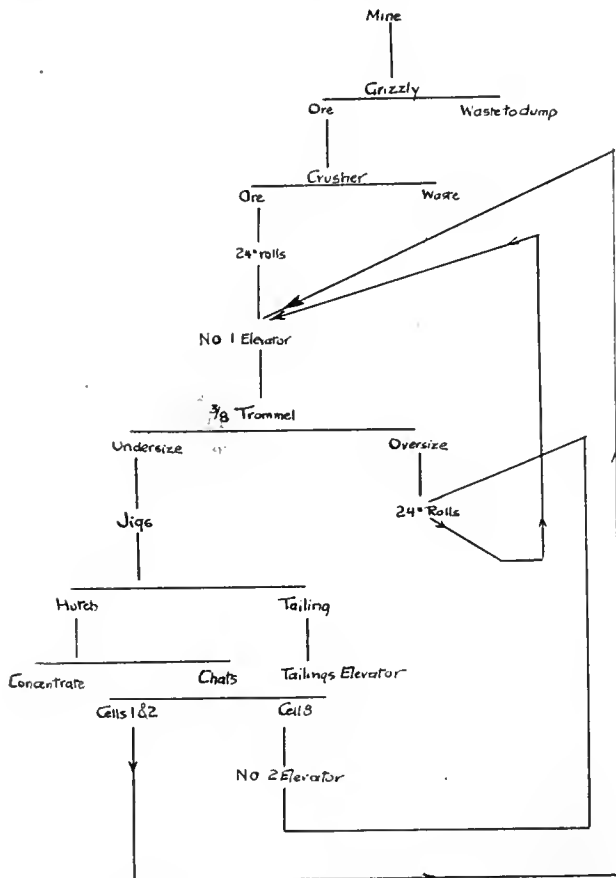

COPPER SITUATION AND THE NICHOLS REFINERY.—EARNINGS OF FEDERAL MINING & SMELTING CO. AND BUTTE & SUPERIOR.—CANADIAN NICKEL CORPORATION ORGANIZED IN LONDON.

A holiday on Friday in the summer reduces a New York business week to little more than three days. Early last Thursday the exodus began from the business districts, and on Saturday not even the department stores were open. This was not a matter of moment in the copper metal market, however, for no business had been done for some time before, small lots of copper changing hands at 14½¢ and 14¼¢. per pound, and the large sellers holding firm at 15¢. without any offers. It is hoped now that buyers will come back into the market after the Copper Producers' Association report is out on Tuesday. Exports during June are given at 27,815 tons, as compared with 26,457 tons during June 1912. The Nichols refinery has been out of the producing list ever since the beginning of the strike there, so that deliveries will be correspondingly decreased for this month. The foreign market, which has been chiefly responsible for the good statistical position of the metal, has struck a snag in the renewal of war in the Balkans, with an even better chance than before that the leading powers may become involved. Aron Hirsch & Sohn began offering September copper in London at lowered prices, though the cables do not give the exact figures. The report has been circulated that a Boston operator has formed a syndicate to engineer a slump in metal prices. The foreign statistics are good, the fortnightly British report showing a decrease of 4,000,000 lb. in stocks. The visible supply in England, France, and afloat thereto was 28,142 tons on July 1, a new low level for recent years, and stocks at Hamburg, Bremen, and Rotterdam shrank to 10,054 tons. But no amount of favorable statistics serves to alter the fact that consumers are not buying and do not seem to care what stocks are.

The shut-down of the Nichols refinery means that about 1,000,000 lb. per day is being kept off the market, and the management has at least room to congratulate itself that its difficulties coincide with a non-existent market, rather than one in which copper is in brisk demand at 16 or 17¢. per pound. Exports from the United States for the half year ended June 30 are given as 193,936 tons, a new high record which exceeds the figures for last year by over 21,500 tons.

Net earnings of the Federal M. & S. Co. for its third quarter, ended May 31, are given as \$204,000, the earnings for the 9 months being \$724,000, or \$4000 above the sum required for a full year's dividends on the present 6% basis. Butte & Superior made earnings of over \$60,000 in June, according to a report from Butte, where D. C. Jackling is quoted as saying that the mill recovery was slightly over 90% in June and that the second section will be completed soon. Tonopah Belmont reports earnings of \$481,831 for the quarter ended May 31, and a total net income of \$493,707.

An important new company which has been launched in

FLOW-SHEET OF A 50-TON MILL WITH 8-COMPARTMENT JIG, WISCONSIN.

district during the last week of June, and stated that operations will be started all over the properties. This means that several hundred miners will be employed in the mines already developed; that a great deal of new machinery will be installed, and that several new buildings will be erected at once. These developments are leading to one of the greatest mining booms ever experienced in the northern half of the Wisconsin zincfield.

R. W. Hunt & Co., engineers, for the Fields Mining & Milling Co., recently made one of the best finds of zinc ore, in the Crawhall mine at Shullsburg, which has as yet been reported in this district. The discovery was made on the Thompson land adjoining the Crawhall farm, from which the owner has been drawing \$5000 per month royalty. The Company has been paying monthly dividends of \$28,500. The ore is declared by officials of the Company to exceed in richness and quantity the deposits proved with drill in the early stages of development on the Crawhall land.

The O. P. David mine was the principal producer in the Montfort district. At Mifflin, the Coker, Ellsworth, Rundel, Peacock, and Lucky Six mines furnished the bulk of the ore. At Linden, Ross Bros., Glanville, Optimo No. 1 and 2, and the Hinkle and Weigle mines were the active producers. The East End mine at Platteville made the best showing; while the Klar-Piquette and Homestead mines

Montreal and London is the Canadian Nickel Corporation, Ltd., which has issued \$10,000,000 worth of 6% debenture stock and \$20,000,000 in common stock. The Company has acquired 17,500 acres of mining property in the Sudbury district, and announces that it will mine 540,000 tons per year at a cost of \$6.60 per ton for mining and treatment, extracting an average of 30 lb. of nickel, 12 lb. of copper, and \$1 worth of precious metals per ton of ore, thus making a profit of \$2,678,400 per year. This all reads very well, but it would be useful to know how many tons of ore are available and how certain are processes of treatment. It has been understood that the Hybinette process was to be employed, but recent reports appear to be adverse to the success of this process, and the International Nickel Co., which has so far controlled the nickel market, does not show any signs of worry as yet.

BOSTON

BUTTE & SUPERIOR AND ELM ORLU EXTRALATERAL RIGHTS.—LAKE COPPER CO.—LEACHING NEVADA-DOUGLAS ORES.—BOSTON & CORBIN COMPANY.

The principals of the Butte & Superior and Elm Orlu properties in the northern part of Butte are trying to avoid litigation over extralateral rights. W. A. Clark has had Walter Harvey Weed, and the Butte & Superior has had J. W. Finch examining the ground, with the view of reaching a basis of settlement. One report stated that the Butte & Superior company would buy the Elm Orlu property, but this was denied by the former interests. It is believed in Boston that, while the feeling between the two parties may not be any too cordial, there is a disposition on both sides to avoid a lawsuit.

Thomas T. Read, associate editor of the *Mining and Scientific Press*, whose offices are in the Woolworth building, New York, has been in Boston during the past few days meeting a number of people connected with the Lake Superior copper mines. Much interest is expressed here in the forthcoming visit of Mr. Read to the Lake district, where he will make a study of conditions. There are persistent rumors of a possible Lake Copper Co. and South Lake Mining Co. merger. Recently, on account of the slump in the former, the two stocks, with the regulation Michigan capitalization of 100,000 shares each, have sold within a fourth of a point of each other. J. R. Finlay, three years ago, gave the Lake mine a valuation of \$3 per share, and questioned the prospect of it ever paying a dividend. It is stated that a veteran mining magnate of Utah became so certain of the prospects of Lake when the stock was selling up in the eighties, that he bought \$300,000 worth of it. One strong point in the Company's favor is that it still has \$22 per share callable on assessments. But this is a hard time to realize on assessments. In the fall of 1910, a banking house here underwrote 1000 shares at a price which netted \$26,990. Yet a big fuss was raised about the brokers getting the stock too cheaply. When the Lake Copper Co. was organized 55,000 shares went to the original holders of the land, and 15,000 shares were sold at \$3 each. Later, rights to 10,000 shares were awarded to stockholders at \$6. Then, in order to continue development work, 2000 shares were sold at \$25 each. Two thousand shares were afterward sold at \$41, and 1000 shares at \$51 to \$53. Four years ago conditions at the Lake mine were such that the best Boston authorities were willing to commit themselves incautiously to extravagant statements about its prospects. Less than a year ago the leading financial paper here, in answering a far Western correspondent, said: We believe that purchases of Lake Copper shares around 37 will prove to be profitable, provided that you have patience. The same paper pointed out in March 1910 that Lake had a chance of becoming the largest dividend-payer in Lake Superior, next to Calumet & Hecla.

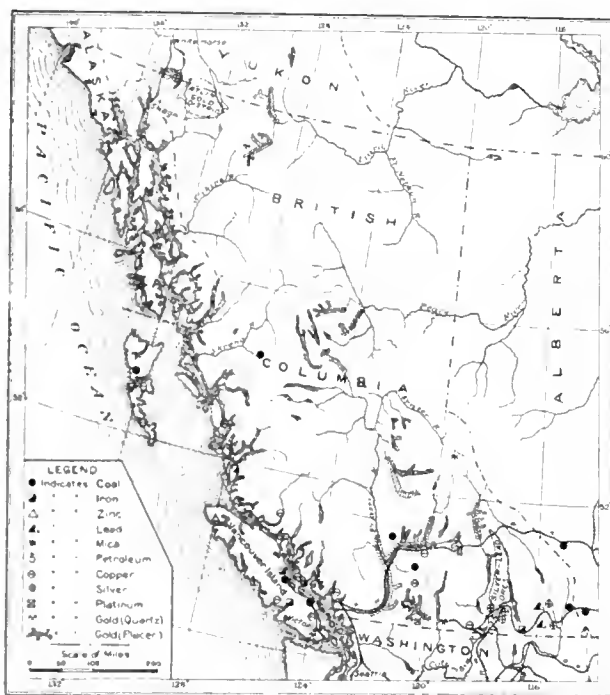

The neatness and dispatch with which the reorganization of Boston & Corbin has been effected is still the subject of comment in Boston. Notwithstanding dullness and distrust, 39,250 shares were taken over in the reorganization, leaving the underwriters with 10,000 shares.

VANCOUVER ISLAND

REVIVAL OF METAL MINING.—PTARMIGAN MINE.—TYEE SMELTER TO RESUME OPERATIONS.—WEST COAST DISTRICTS.—COAL MINING AND LABOR SITUATION.

For the past several years the mining industry on Vancouver island has been confined to coal mines. Previous to 1908 the Tyee, Lenora, and Richard III properties were in active operation at Mount Slicker, and between the years 1900 and the fall of 1907 these three properties had produced about \$2,500,000, the ore averaging about \$3 gold, 4 oz. silver per ton, and 5% copper.

There are indications now that metalliferous mining will take a new lease of life on the island, and several of the partly developed prospects can and will be reopened by companies having ample capital and managed by mining engineers possessed of the experience and energy necessary. The resumption of work is being shown by the operations at present going on near the head of the Great Central lake on the Ptarmigan mining property, which is the same as that originally located as the Big Interior. When this property was opened in 1899, the facilities for transportation were different from what they are now;

MAP OF BRITISH COLUMBIA.

In fact, a rough prospector's trail about ten miles in length, over which a man had to pack all his supplies on his back, was the only means of approach from the Great Central lake, in the interior of the central portion of Vancouver island. From that point to Alberni, on the west coast, the means of transport were also of the crudest, so that unless the ore had been of an exceptionally high grade, it was impossible at that time to undertake serious development. But today, with a good wagon-road connecting Great Central lake with Alberni, and an aerial tramway connecting the mining property with the head of the lake, warrants opening this property and shipping the ore, even though it be low grade.

At Alberni the shipper has choice of two routes to the smelter, either by water or by the Canadian Pacific railway. H. H. Johnson, manager for the Ptarmigan Mines, Ltd., of Victoria, is at present at the property, and is arranging for the erection of the aerial tramway that served the Tyee Copper Co. in transporting the ore about four miles from the Tyee mine to the siding of the E. & N. railway, which was taken down some time ago.

It is reported on reliable authority that, on the return of W. J. Watson, manager of the Tyee smelter, from England, the plant will be blown in again in the near future. In fact, at the present time workmen are renewing the piling at the smelter's dock, and preparations are

being made in a quiet way to have the plant in readiness for operation. It is proposed that ore from the Ptarmigan mine will form a nucleus for the supply to the smelter, and from reliable information it is figured this property should furnish a large tonnage of ore of medium grade.

There are on the west coast of Vancouver island, in the mountains adjacent to Clayoquot, Kyoquot, Nootka, and Quatsino sound, quite a large number of occurrences of copper-bearing ore discovered in 1898 and 1899, that have never been developed beyond the assessment-work stage, sufficient to 'crown grant' the properties. From several of these during that time I obtained samples from outcrops and shallow prospect holes, that carried from 5 to 10% copper. Because of lack of capital and transportation, high smelter rates, and the further fact that, on the Alberni canal, two properties which had considerable capital expended in development, which did not result satisfactorily, that portion of Vancouver island has since been neglected, but really presents an attractive field for further prospecting.

The situation with regard to coal mining for the past seven months has been anything but satisfactory. In the first place, a strike occurred at the mines of the Canadian Collieries (Dunsmuir), Ltd., and about two months ago, when this had become practically settled, and the company was able to mine a normal tonnage from its Cumberland mine with non-union men, the United Mine Workers of America called a strike at Nanaimo in the mines operated by the Western Fuel Co., notwithstanding that the majority of the miners working for the Company were not members of the U. M. W. A., and that they were all working on an agreement with this Company which does not expire until next September. To a disinterested person, it appears that the main result from these labor troubles has been to enable the operators in the state of Washington to work to full capacity in order to furnish the markets heretofore supplied by the Vancouver island collieries, and, besides, to place the miners in a position where they draw strike pay from the union instead of their regular wages from the collieries. Recently members of the Vancouver Board of Trade tendered their good services in an effort to settle the differences between the colliery companies and the miners. This attempt was futile because the Canadian Collieries (Dunsmuir), Ltd., was operating its Cumberland mines to the extent of mining about 2000 tons of coal per day, and, although the Company was not operating at the Extension mines except in a small way, it did not recognize the existence of any strike, while the Western Fuel Co. declined the services of the Vancouver men on the ground that the miners had broken their contract, and so far as the Company was concerned there was nothing to arbitrate. The daily papers announce that the Hon. T. W. Crothers, Minister of Labor in the Dominion Government, is on his way to Vancouver island to investigate the labor conditions, and it is earnestly hoped that his efforts to bring employers and employees together and settle the present difficulties will be successful. There has been almost an entire absence of the scenes and acts of violence which usually accompany labor troubles. In fact, when the strike was first called, opinion generally expressed was against the action of the men, and especially with regard to breaking their contract, when they acknowledged they had no cause for complaints against the Company. Apparently it was purely and simply a case of a small minority who were members of the U. M. W. A. influencing the majority who were non-members by the fear of being called 'scabs.' The latest report is that miners are coming from England, and almost daily new arrivals reach the works on the Canadian Collieries (Dunsmuir), Ltd., and start work. The mines of the Western Fuel Co. at Nanaimo, Pacific Coast Coal Co. at South Wellington, and the Vancouver Nanaimo Coal Co. at the Jingle Pot colliery near Nanaimo, which includes all the collieries in that portion of the island except the Extension, are shut down, owing to the strike, while at the Extension a few men are working. Whether any attempt will be made to operate there with an increased force is not yet known.

KALGOORLIE, WESTERN AUSTRALIA

FEELING AS REGARDS THE MINING INDUSTRY.—SONS OF GWALIA AND GREAT FINGALL MINES.—FRASERS GROUP AND DIAMOND-DRILLING.—BULLFINCH AND VICTORIOUS DEVELOPMENTS.

W. J. Loring, head of Bewick, Moreing & Company, has just visited this state after an absence of three years. He was quite optimistic regarding the possibilities of gold-mining, and said that he could not understand why so many people were the reverse. He was enthusiastic regarding the deep developments on the Sons of Gwalia and the Great Fingall Consols. At the former property he stated that, in addition to the \$75,000 expended on new plant during 1912, another \$50,000 would be spent during 1913 and 1914. Wood-burning suction-gas generators had proved so economical at the Queen of the Hills at Meekatharra that his firm would gradually supersede steam-engines for driving treatment plants on all its mines. Developments at the Sons of Gwalia were highly satisfactory, and production and dividends could be maintained at their present rate for 3½ years, while the alterations were being made. With regard to the Great Fingall, the equipment of the internal shaft at No. 13 level would be completed by September, when ore down to No. 18 level would be available for the mill. The new ore-shoot at No. 17 and 18 levels has been proved for a length of 400 ft. to be worth \$10 to \$12.50 per ton, averaging 8 ft. wide. Referring to the volatilization process of gold saving introduced on the Gwalia Consols by Ben Howe, Mr. Loring was satisfied that it would solve the difficulty of treatment of refractory ore containing arsenical pyrite and antimony, which has been the bugbear of the Gwalia Consols, Lancefield, and Transvaal mines, which have not been satisfactory for several years.

While at Southern Cross, Mr. Loring took an option on the Frasers group of mines, which have been practically at a standstill for a dozen years. On the strong recommendation of the government geologist, Harry P. Woodward, backed by the Government mining engineer, A. Montgomery, the Minister for Mines, P. Collier, offered to subsidize any local syndicate and supply a diamond-drilling plant and a supervisor to test the line of lode by a series of 10 bores to depths down to 1000 ft. This work was started in January, and the first bore has been completed. The cores from 538 to 542 ft. assayed \$21 per ton, and from 958 to 976 ft. cut a second lode which showed visible gold at 968 ft., but assays have not yet been published. Mr. Collier has promised Mr. Loring that if the latter can raise the money to sink a shaft and develop at 1000 ft., the Government will subsidize the venture to the extent of \$30,000. The mines have already produced \$3,625,000 from 325,000 tons, and the deepest workings are only 366 ft. deep, and little work has been done at that depth. There are three lodes in the property, but only one has so far been developed. The ore-shoot has yielded ore for a length of 4000 ft. and a width up to 20 ft. This seems to be a most promising venture, and may lead to this state being more exploited by capitalists in the future than in the past.

Detectives have failed to find any clue to the robbers who stole \$15,000 worth of retorted gold from the smelting-room of the Bullfinch mine. The carelessness of the management may be gauged from the fact that with nearly \$75,000 of gold amalgam and precipitate to be treated, the three men held up by the robbers only earned \$2.70 per day each. The mine is looking well, and development is being done on five different lodes, stoping covering a width of 15 to 60 ft. The plant is being increased by an additional 5 stamps and a tube-mill. Fred Morgan, the manager, states that he could easily provide ore for double the capacity of the mill. When the present plant is complete, 6000 tons per month will be treated, and a minimum profit of \$50,000 per month will be made. The winze in the Associated Northern-Victorious leases at Ora Banda are now down as follows: No. 1, to 45 ft., averaging \$10.25; No. 3, to 49 ft., averaging \$34; and No. 4, to 55 ft., averaging \$33 per ton. At a depth of 25 to 30 ft., telluride was showing in both No. 3 and No. 4 winzes at the junction of the oxidized and sulphide zones, but did not continue.

General Mining News

ALASKA

JUNEAU

Though the chief object of the Alaska Gold Mines Co. is to prepare the mine for production, the work has disclosed some interesting developments. It will be recalled that the Alexander level is being continued east at an average depth of about 1500 ft. Cross-cuts from this, through the orebody, which are being driven every 200 ft., continue to show that the Company will develop from a point about 2000 ft. east of the cross-cut, and for a distance of at least several hundred feet, a body of ore, averaging higher in grade than the estimated average of the mine. Even a small body of ore of such a grade as indicated in these cross-cuts, that is assaying over \$3 per ton, as against the estimated average of \$1.50 for the whole mine, would do much to 'sweeten' the average of the whole. General construction work in all departments continues at a satisfactory rate. The cement for the dam is arriving by this time; the cement work-house above the dam is practically built, and plans for the upper power-house are almost finished. On the Sheep creek division, work continues on the re-location of the railroad; bunk and mess-houses are practically completed; the tunnel, which, it will be recalled, cuts the deposit about 700 ft. below the Alexander level, and will be the main extraction way, keeps up its rapid driving of over 500 ft. per month.

NOME

A new dredge of 1½ cu. ft. capacity close-connected buckets is being installed at the mouth of Peluk creek. It will be equipped with certain improvements adapting it for beach dredging, and is the second to be erected here by the American Dredge Building & Construction Co. Probably a dredge will be erected this season on Hastings creek, above Saunders creek, and another on Sunset creek. A new interest is being awakened in this branch of mining.

ARIZONA

COCHISE COUNTY

At the Calumet & Arizona smelter the total production for June was 4,400,000 lb. of copper, a decline of more than 500,000 lb. During the latter part of the month the old smelter plant was entirely shut down and the second of the new blast-furnaces blown in. Both the furnaces are handling about 1400 tons of ore daily. Three converters are in use in the new plant. The work of clearing the ground around the old plant, preparatory to dismantling it, has been started.

GILA COUNTY

(Special Correspondence.)—The men employed on the transmission line between the Roosevelt dam and Superior by way of Miami, consisting of about 25 white men and 75 Indians, are now at the head of Queen creek box cañon, a mile from Superior. As the concrete foundations for the towers are laid, a road gang makes a four-foot trail at a wagon grade, and slight widening of the trail in the future will transform it into an excellent wagon-road. This will fill in the gap between Iron's ranch and the town of Superior, thus placing Globe, Miami, Superior, Florence, and all the intermediate towns and mining camps on a direct line of communication, besides bringing Ray and vicinity into closer relation with the Miami mining district. When the electric transmission line reaches Superior, it may be considered feasible to build a branch line to the Calumet & Arizona property 2½ miles south, whence a transmission line leads to Winkelman, where the power is generated. With such an arrangement, temporary disability at either the Government plant at Roosevelt, or the Ray Consolidated power-plant at Winkelman, could be relieved at the other end. A recent report of a discovery of great richness in Powers gulch seems not to be borne out by subsequent investigation. Beaude-laire, who brought the ore to Globe, where assays showed 1700 oz. silver and \$200 gold per ton, did not claim, as

reported, that he had any quantity of the ore, which was a small picked sample.

Miami, June 30.

PIMA COUNTY

The Calumet & Arizona Mining Co. has purchased the Cornelia mine, which will probably be worked by steam-shovels.

YAVAPAI COUNTY

At the Arkansas & Arizona mine, in the Jerome district, three new 150-hp. boilers and a hoist with 2000-ft. capacity are being installed. The cross-cut on the 800-ft. level of the United Verde is near the point where it will be cut by the new shaft. Good orebodies have been opened recently in the Copper Basin mine, near Prescott. This is controlled by Phelps, Dodge & Co. New machinery is being erected for the mill at the Y-P mines, near Senator, and stamps are now ready to begin work. The 800-ft. tramway from the dump to the plant is nearing completion. About 10,000 tons of ore accumulated from former operations will be treated.

CALIFORNIA

AMADOR COUNTY

At the Argonaut mine, a drift from the 3900-ft. level has been extended 300 ft. into rich quartz. The May clean-up was about \$50,000. The Wildman-Mahoney property will probably be sold to an Eastern syndicate.

BUTTE COUNTY

The Drexler dredge is doing good work near John Adams, and the White ranch is to be dredged shortly. A shaft is being sunk to open gravel at the old Hendricks property at Thompson's Flat, near Oroville. A 15-hp. gasoline hoist has been installed.

CALAVERAS COUNTY

Rich ore has been opened in the Tanner mine, and attention is being directed to the east side gold belt near Murphy's. The 60-stamp mill of the Lightner company is being overhauled.

NEVADA COUNTY

F. M. Spaulding, of Los Angeles, has completed arrangements for reopening the old Richlan gravel mine on Wet hill. The lease of the old company has been taken over by the Major Gold Mining Co. A new shaft will be sunk to open the channel, and it is estimated that it will have to be sunk about 150 ft. to reach the gravel. The new shaft will be near the old Emplre shaft on the Ragon place through which \$300,000 was taken out. The new company owns about 7000 ft. along the Manzanita channel.

PLACER COUNTY

Representatives of the Guggenheim interests have men at work at Poverty Bar, near Butcher ranch, to ascertain whether the gravel is sufficiently rich to warrant the purchase of the property. They have an option until August 1. The company owning the property has stopped work on the gold dredge for the present.

SANTA CLARA COUNTY

(Special Correspondence.)—It is expected that changes in management of the Quicksilver Mining Co. will lead to a vigorous attempt to rejuvenate the famous old New Almaden mines. C. A. Nones, who as president has been in control for several years, has been removed and W. H. Landers has been appointed manager. The Company has paid no dividends for some time, and it is now reported that it was kept going by sale of farm lands. A serious shortage in accounts is alleged against the old management. In the meantime, Mr. Nones has been declared bankrupt. Some months since, the stockholders formed an insurgent committee and, acting for them, a careful report upon the property was made by Mr. Landers, assisted by Clifford G. Dennis. The old mine has been worked to a depth of 2400 ft. and has yielded handsomely, though of recent years the grade has been extremely low; roughly ½%. While extensive tracts of mineral-bearing land are owned, there has been little effort to develop new orebodies, and there is practically no ore in sight. About 4½ miles north are old workings from which at one time quicksilver to the value of \$60,000 was won, and in the ground be-

tween them are abundant evidences of mineralization, and many small abandoned workings. Mr. Landers has recommended that serious efforts be made to reopen some of this ground. When the old workings were abandoned, 1½% constituted the lower workable limit of ore, and it would certainly seem probable that since ½% ore has paid a profit for some years, it is worth an effort to reopen the ground. One curious and exasperating difficulty is the presence of carbon dioxide, but it is expected that means will be found for meeting this difficulty and the mine will again become an important producer.

San Jose, July 7.

SHASTA COUNTY

The Noble Electric Steel Co. is employing 50 men, and the furnace is producing 25 to 30 tons of iron per day. Coke is now being used instead of charcoal.

SIERRA COUNTY

Since the vein was cut in the North Fork mine, it has widened from 2 to 13 ft., and is all payable. The drift will soon be under the rich shoot opened many years ago. At the Tightner, a shaft is to be sunk from the lower adit, on one of the rich ore-shoots. Active development is under way at the Wisconsin gravel property near Forest City.

SISKIYOU COUNTY

It is stated that the Blue Ledge copper-gold property, near the Oregon line, has been sold to New York people. The Osgood quartz claims and the Nigger Boy mine, on Ash creek, have been acquired by Oregon and Ohio people.

TRINITY COUNTY

The Trinity Consolidated Hydraulic Mining Co. is operating a large force of men at both the Union Hill and Hupp hydraulic mines.

YUBA COUNTY

The Elks Gold Mining & Milling Co. has secured a two years' lease of the properties of the Red Ravine Mining Co., near Indian ranch. New machinery is to be installed and active work will commence early in August.

COLORADO

PUEBLO COUNTY

The Colorado Fuel & Iron Co. will increase its equipment of electrical apparatus by the addition of 200-kw. and 300-kw. rotary converters, a 50-hp. motor, three 110-kva. and three 150-kva. transformers, and switchboard panels and accessories. The apparatus will be furnished by the General Electric Company.

TELLER COUNTY (CRIPPLE CREEK)

According to local statistics, the gold production was as follows:

	Tons.	Av. val.	Gross val.
Golden Cycle, Colorado City....	34,000	\$20.00	\$ 680,000
Portland, Colorado City	9,950	22.00	218,900
Smelters, Pueblo and Denver....	3,850	65.00	250,250
Portland, Cripple Creek	13,600	3.00	30,800
Stratton's Independence	11,800	2.36	27,848
Colburn Ajax	4,245	2.59	11,674
Gaylord Dante	1,800	3.00	5,400
Kavanaugh-Jo Dandy	1,500	2.30	3,450
Wild Horse	1,300	3.20	4,160
Isabella	625	2.00	1,250
Total	82,670		\$1,233,732

El Paso company and lessees shipped 100 and 48 cars of ore, respectively. The Cresson mine, on Raven hill, produced about 4000 tons. Eight sacks of ore, valued at \$1000, were stolen from a freight car between Cripple Creek and Colorado Springs. Lessees at the Deadwood, Sitting Bull, Rising Sun, Vindicator, and W. P. H. properties are doing fairly well. An experimental cyanide plant is being erected at the Vindicator to treat dump ore. The flow of water from the Roosevelt tunnel is now 6735 gal. per minute. The recession during June was about 72 in., and water-level is 30 ft. below No. 11 level of the Gold Coin shaft.

THE SAN JUAN

Ore and concentrate shipments from Ouray during June

were as follows: Camp Bird, 650 tons; Wanakah, 650; Atlas, 325; Bachelor district, 168; Jumbo, 24; Haagsma-Hall, 25; Revenue, Lannon lease, 48; and American Nettle, 23; making a total of 2011 tons.

Shipments from Silverton were as follows: (1) concentrate, Sunnyside, 818 tons; Iowa Tiger, 282; Vinyard & Co., 159; Frisco Tunnel, 232; and Gold King, 217; a total of 1708 tons; (2) crude ore, Gold Tunnel, 125; Celtic Leas-

LOOKING TOWARD OURAY FROM CAMP BIRD MILL.

ing Co., 25; Dives, 132; So. Expl. & Mining Co., 306; Al-lerton, 65; Scotia, 44; Frank Hough, 40; Boston, 22; and Bazanella, 20; a total of 779 tons.

IDAHO

BLAINE COUNTY

Good ore has been opened in the Plughoff & Reed claims at Glendale. At one place it was cut after driving through 40 ft. of soft ground, and shows 7 ft. of silver-lead ore. Sixty feet west a shaft has opened more ore of a similar character. The vein is well defined, and so far is continuous for 70 ft., in granite country.

BONNER COUNTY

Nearly 100 men are employed now by the Idaho-Continental Mining Co. and work of preparing the ground for the concentrator at the mine and the power-plant, 14 miles beyond Porthill, is being rushed as rapidly as possible.

SHOSHONE COUNTY

(Special Correspondence.)—The worst mine cave-in ever experienced in the Coeur d'Alene has resulted in an almost complete shut-down of the Hercules. The collapse of the galleries took place on June 4, closing all the workings above the No. 4 adit. An effort is being made to resume operations in the levels from the winze, and some ore is being removed.

Operations at the mill of the Idora Hill Mining Co., on Sunset peak, in the Coeur d'Alene region, have begun. The mill is designed to handle 50 tons per day, but it is believed that the capacity will approach 100 tons when it is in full working order. The plant, and the tramway connecting the mill and the mine, are operated by electricity. Arrangements are under way for the consolidation of the Reindeer Copper & Gold Mining Co. and the Copper Queen

Mining & Milling Co., Ltd., whose respective properties adjoin, in the Coeur d'Alene. It is proposed to organize a new corporation with a capitalization of 2,000,000 shares.

Spokane, Washington, July 3.

Fred T. Greene, an engineer for the Amalgamated Copper Co., of Butte, Montana, has made a report on the National copper mine, near Mullan. The report is as follows: Below present adit level, partly developed, 883,990 tons, valued at \$910,066; probable ore, 875,400 tons, valued at \$2,074,698; possible ore, 1,830,620 tons, valued at \$4,338,569; total, \$7,323,333. Above adit level, partly developed, 247,890 tons, valued at \$587,499; possible ore, 207,520 tons, valued at \$491,822; total, \$1,079,321. This makes a total value of \$8,417,890. A contract has been let for a 600-ft. raise from the adit, and should be completed by the time the mill is ready next February. A boarding and bunk house of 200 men capacity is being built. Charles McKinis is general manager.

Early on July 4, somebody dynamited the flume of the Bunker Hill & Sullivan mill, tearing a hole 10 ft. wide on one side and causing a great loss of water. After an hour the water was shut off at the intake. No arrests have been made. The Snowstorm Mining Co. paid a dividend amounting to \$22,500 on July 10, making a total of \$1,169,617 to date.

MISSOURI

LAWRENCE COUNTY

The Grasselli Chemical Co. has awarded contracts for drilling 300 acres of its land near Statte City. At one time this property produced a good deal of ore from shallow depths, and now the deeper levels will be prospected.

MONTANA

JEFFERSON COUNTY

(Special Correspondence.)—A report is to hand that lessees at the Ruby mine, near Basin, have shipped four carloads of ore valued at \$120,000. This was mined by driving a short drift in new ground from old workings. This mine formerly was a good gold producer, and was bonded to P. H. Dowling by W. A. Clark about six years ago. The former soon paid off the bond of \$75,000, and recently leased the property to some Butte miners, who opened this rich ore.

Basin, July 5.

SILVERBOW COUNTY

(Special Correspondence.)—The usual quarterly dividend of the Tuolumne Copper Mining Co. was not declared, as profits were not sufficient to justify paying out \$80,000. The property is a small one, but is surrounded by good mines. At a meeting of the directors the superintendent stated that a rich shoot had been opened on the 2200-ft. level. It is 8 ft. wide and assays 7 to 12% copper. In the southeastern part of the district about 1100 acres of ground have been acquired by one of the leading companies at a cost of over \$1,000,000.

Butte, July 5.

NEVADA

CHURCHILL COUNTY

During May the Nevada Hills mill treated 4260 tons of ore averaging \$12.45 per ton, with a residue loss of \$1.56 per ton. The total recovery was \$46,403, at a cost of \$28,345, leaving a profit of \$18,057. There is \$30,000 owing to the bank, while cash, supplies, concentrate, and absorption in plant are valued at \$110,000.

ELKO COUNTY

(Special Correspondence.)—At the Bluster mine, timbering heavy ground has been completed, and development is again under way. At a point in the vein 225 ft. south of the main cross-cut adit the drift was driven on what was supposed to be the foot-wall. It was opened at this point and ore averaged \$30 per ton across 3 ft. About 3300 ft. of work has been done in the mine. At the Flaxie a drift from a depth of 53 ft. in the winze is out 30 ft. in good ore. Specimen ore has been opened in the Buckeye. Fair developments are reported from the True Fissure and Stormy groups.

Jarbridge, July 8.

LYON COUNTY

(Special Correspondence.)—Reports from the superintendent of the Nevada-Douglas mine continue to be encouraging. The 700-ft. level in the south end of the Ludwig has been driven for the last 50 ft. in ore which averages about 15% copper, and some specimens of metallic copper are being obtained at this point. On the sixth level a big tonnage of high-grade ore is being stoped, and it is hoped to open an extensive orebody at this point. On the 100-ft. level the drift which is being driven to the north beneath the wide gossan outcrop is looking favorable; the last 20 ft. has been driven through leached gossan which widens out as the breast advances. There is every probability of finding a good-sized body of ore of a secondary nature below. A small force of men has been put to work in the Casting Copper adit, and shipments from there will be resumed. The proposal to build a smelter for the Nevada-Douglas has been definitely abandoned, as the experiments with leaching

MAP OF NEVADA.

made by the staff have resulted so favorably that W. L. Austin was engaged to study the problem, as well as similar work elsewhere. Mr. Austin has reported that while mechanical difficulties are being experienced in leaching work at the Bullwhacker and Butte-Duluth, there is every probability that they will be successfully overcome and that leaching by means of sulphuric acid can be done on these ores at a cost not to exceed 10c. per pound. The ore, crushed to 16 mesh, will be leached with a 12% solution of sulphuric acid, giving a 90% extraction, the copper being precipitated from the solution by electrolysis. It is the intention of the management to proceed with the construction of a leaching plant, and the ore in the Douglas Hill group will be treated in this way.

Mason, July 3.

During the week ended June 2, the Mason Valley smelter treated 4422 tons of ore, and shipped seven cars of matte. The Oakland Copper Belt has opened 5 ft. of ore. Ore on the dump averages 7% copper, 5 oz. silver, and \$2.50 gold per ton. At the Yerington mountain, the shaft to connect No. 3 and 4 adits is down 600 ft. Regular shipments are made to the smelter. A gasoline hoist has been installed at the Blue Jay.

NYE COUNTY

The *Tonopah Miner*, which is now in its twelfth year of publication and has always been optimistic about Tonopah mines, states that the gross production of the district for the first half of 1913 was \$1,210,889. During the week ended July 5 the output of eight mines was 11,715 tons valued at \$259,345. On the 750-ft. level of the new shaft the Tonopah Extension has opened a new vein in the north cross-cut. So far it is of a low-grade character. The south cross-cut on the Montana-Tonopah 55-ft. level went through 12 ft. of quartz, showing good ore in places, and is thought to be a faulted portion of the south vein. The Halifax 1000-ft. level has cut some rich veins of sulphide ore. On the 1166-ft. level of the Belmont, the north cross-cut opened the western extension of the shaft vein 375 ft. west of the other shoot being developed on this level.

At Manhattan the Big Four is producing about 100 tons per day, but this will be increased when the conveyor is installed to handle the reject from a trommel working below the crusher. This will act as a sorting station and prevent waste going to the stamp-mill. The lessees at the White Caps are still shipping high-grade ore to Tonopah. The Earl claim of the Brady leases is improving on the 350-ft. level.

STOREY COUNTY

It is probable that a 50-ton plant consisting of Kinkead crushers, amalgamating plates, and concentrating tables will be erected on Cedar Hill to treat ore from the Sierra Nevada property. Walter Techow, of the Kinkead Milling Co. and Ophir cyanide plant, will be in charge.

WHITE PINE COUNTY

One round of shots in the Morris and Bunker Hill mines of the Giroux company, at Ely, is said to have broken down 30,000 tons of ore. As a result the operating force was reduced by laying off about 125 men. Until now, it is stated that while the mines have been producing 1000 to 1200 tons of ore per day, much of it has been taken out in further developing the ore deposit. Now the development has reached the stage where the best features of the caving system can be followed and cost of mining will be greatly reduced.

NEW MEXICO

The output of coal in New Mexico in 1912 was the largest ever made, according to the U. S. Geological Survey. The production increased from 3,148,158 short tons in 1911, valued at \$4,525,925, to 3,536,824 tons in 1912, valued at \$5,037,051, a gain of 12.3% in quantity and of 11.3% in value. In the Raton field, 11 mines produced over 100,000 tons each, two producing over 400,000 tons. The San Juan River field, in the northwest, has an area of 13,000 square miles.

GRANT COUNTY

The Chino Copper Co. recently made an experimental shot in one of its open-cut mines at Santa Rita and the result was, it is said, entirely satisfactory. Three adits, some 10 or 15 ft. apart, were driven into the mine a distance of 45 ft., each connected at the ends by a drift about 50 ft. long. In this drift, near the end of each adit, 53,000 lb. of high-grade powder was packed. The blast was fired by electricity. This method cost between \$7000 and \$8000, but is expected to simplify mining there, where 90% of the ore can be moved by steam-shovel work.

OREGON

JACKSON COUNTY

(Special Correspondence.)—A 20-ton mill is being erected at the Nellie Wright mine, in the Gold Hill district. It will be driven by electric power. The ore is worth from \$9 to \$18 per ton. The Blossom mine, in the same district, is opening well. The Cinnabar has been opened by two adits, driven to depths of 320 and 180 ft., respectively. Drifts from these have opened a large orebody, assaying high in mercury. The property is being examined by two engineers. After an idleness of 30 years the old Alice mine, on Kanes creek, is being reworked.

Philomath, July 4.

UTAH

BEAVER COUNTY

The Majestic Mines Co. owns, near Milford, 25 claims containing copper and silver-lead ores. Monthly profits range from \$3000 to \$5700. The deepest shaft is down 600 ft., and has opened silver-lead ore 100 ft. below water-level. The shoot of copper ore in the Old Hickory is fairly extensive and contains about 75,000 tons. Shipments total 75 tons per day.

JUAB COUNTY

For several months the Tintic Standard 1000-ft. level has been driven on a contact between quartz and lime, which was of an encouraging nature. Ore was cut, but gas drove the men out. The ore was rich in lead and silver. Similar ore has also been opened in a drift from a winze below the 1350-ft. level of the Eagle & Blue Bell mine. Work is to be resumed at the United Tintic, as the last assessment has been paid off the Company's debt, leaving a surplus for further work.

SALT LAKE COUNTY

During the half-year ended June 30, 1913, the Salt Lake Stock Exchange dealt with 3,499,979 shares, representing a value of \$833,763. These included 62 listed and 22 unlisted stocks.

High-grade silver-lead ore has been opened in the Graham lease of the West Toledo mine at Alta. A cave had been driven into 175 ft. from the mouth of an adit, and six inches of ore was exposed, which is figured to be an extension of the Toledo vein.

The Utah Consolidated Mining Co. has paid a dividend of 50c. per share, amounting to \$150,000. The mine is opening well, and several new shoots of copper have been discovered. One is in the porphyry dike which divides a portion of the Highland Boy limestone. It is small but parts carry 10 to 15% copper. On No. 12 level, 2.4 to 3.4% copper ore is being mined. This mine is the largest lead producer in Utah, and lead ore shipments average 250 tons per day. The shoots, especially in Yampa limestone, are showing well.

SUMMIT COUNTY

The Silver King Coalition Mines Co., Park City, will place in operation in its mines new 2½-ton and 3-ton electric locomotives and a 35-kw. motor-generator set ordered from the General Electric Co. The report of Frank Anderson, engineer conducting surveys for the Silver King Consolidated through the Silver King Coalition's workings, to ascertain if the latter Company has trespassed on the former property, has been returned to the federal district court. The engineer says that, to the best of his knowledge, the Coalition's workings do not enter the Consolidated's ground. This report is believed to be the ending of the present \$750,000 trespass suit. The Consolidated officials say that they will go further down into their own ground and try to discover if there is evidence of trespass there. This work will take many months, as about 1800 ft. will have to be driven.

During the first half of 1913, the Park City district produced 41,095 tons of ore valued at \$1,643,800. Eight roasting furnaces are working at the Ontario mill, and 150 to 160 tons are being treated daily.

WASHINGTON

STEVENS COUNTY

The president of the Chewelah Copper King Co., S. P. Domer, has denied that the mine has been sold for \$350,000, but stated that negotiations are under way with the Granby company, of British Columbia. A recent shipment of ore to the Grand Forks smelter returned 8.65% copper and 41.6 oz. silver per ton. Electric power for the mine and mill of the United Copper Co., near Chewelah, will be available in about two weeks. At present, 100 men are employed. The adit being driven to cut the vein at a depth of 1000 ft., at a distance of one mile, is being pushed forward steadily. It is in 2500 ft., and 180 ft. was driven in June. The shaft is down 600 ft. An engineer for the Guggenheims has been examining the property.

MEXICO**COAHUILA**

(Special Correspondence.)—The condition of the north-eastern states of Mexico, especially Coahuila, Tamaulipas, and Nueva Leon, is as bad as could be. The federal troops are only holding the large towns and are trying to keep open a part of the railroads, meeting with indifferent success. A large percentage of the population of these states, especially the middle and lower classes, is against the present government of Mexico. Mining is almost at a standstill. The Mazapil Copper Co., operating the Coahuila & Zacatecas railway from Saltillo to Concepcion del Oro, in the state of Zacatecas, has been shut down since May 1. This includes mines, two smelters, and railway, throwing out of employment between 3000 and 4000 men. Conditions are steadily growing worse.

Saltillo, June 17.

SONORA

Mine shipments from Sonora during June came well up to the average, there being more than \$2,000,000 worth of ore shipped into Arizona and Texas from various properties. As shown by the statement of the collector of customs at Agua Prieta, the June shipments were: Nacozari, 10,560 tons; Churunibabi, 1522; El Tigre, 92; Panama, 41; San Ygnacio, 21; Vaquero, 41; Sonora, 47; El Temblor, 22; and Alice, 27; making a total of 12,373 tons. El Tigre shipped 71 bars of bullion. Estimated values are as follows: Gold, \$295,800; silver, \$587,300; and copper, \$1,168,900; a total of \$2,052,000.

The wet and dry mills of the Calumet & Sonora mine are working two shifts. Ore is mined on the 400 and 500-ft. levels. The new crusher and sorting belt are working well. About 160 men are employed.

PERU

(Special Correspondence.)—Ferrobamba is shut down for the present. In the Department of Arequipa, many mining properties are of doubtful value, and difficulties in transport, labor, and laws are against good work. As far as the southern portion of Peru is concerned, a promising enterprise is the investigation of the great belt of Silurian slates, which extend from the west side of the main Andean range, to the north and east, in the direction of the Inambari and Paucartambo rivers, where there are gold deposits of a good character.

Casilla, Arequipa, June 14.

The Borax Consolidated, Ltd., of London, England, has petitioned the Peruvian government for certain concessions in the Republic, in return for which the Company agrees to do the following: (1) Construct a railroad or aerial tramway from the borax and salt mines in the province of Moquegua, department of Arequipa, to the city of Arequipa; (2) install near the city or mines a plant to produce 40,000 tons of borax and over, as the demand increases; (3) transport from the mines to Arequipa 1200 tons of salt annually, and return with supplies for the employees of the Compañia Salinera del Peru; (4) erect telephone lines to the mines; (5) employ only Peruvians at their works; and (6) will spend £200,000 on the concession on these works. In return for these proposals, the Company asks that no export duty be placed on borax from the port of Mollendo for 18 years after work commences, all equipment to be imported duty free, and that the towns near the concession will not tax borax production for 18 years.

Schools and Societies

A number of students from the KANSAS SCHOOL OF MINES AND METALLURGY, accompanied by B. L. Wolfe, E. C. O'Keefe, and A. W. Young, inspected the mines, smelters, and mills in the mining district around Joplin, Missouri, and in southeastern Kansas during the first week in July.

The COLORADO SCHOOL OF MINES summer classes open on July 14 and will finish on August 23. There will be four

instructors, and subjects include seven grades of mathematics, civil and mechanical engineering, chemistry, and metallurgy. Fees range from \$4 to \$15 per subject. It is proposed during the coming fall to have a short course in coal-mining.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

WALTER OREM is in New York.

JAMES G. BERRYHILL was in New York recently.

STEPHEN BIRCH is at the Midas property near Valdez.

GRANT H. TOD is on his way to Seattle from Alaska.

A. K. MCDANIEL is making examinations in Alaska.

B. B. THAYER will leave New York for Butte on July 15.

F. W. BRADLEY left Juneau for San Francisco on July 10.

H. F. FAY has returned to Boston from the Lake Superior district.

H. ROBINSON PLATE is making a professional visit to Juneau.

LEVI HOLBROOK is ill with pneumonia at Cambridge, Massachusetts.

F. G. CLAPP sailed for Europe on June 24 for professional work in Hungary.

KIRBY THOMAS has returned from a professional visit to the Cobalt district.

JOHN A. THOMSON will leave Saltillo, Coahuila, Mexico, by way of Tampico, for the United States.

JOHN BAGLEY has been appointed by Governor Lister inspector of mines for the state of Washington.

E. J. VALLENTINE is on a six months vacation and expects to arrive in San Francisco on July 21, on his way from the Malay States to England.

C. H. FULTON and J. BURNS READ, of the Case School of Applied Science, who have been visiting the West, were in San Francisco last Monday.

H. H. ARMSTEAD, president of the Mexican United Co., has gone to Mexico to make an inspection of the Company's properties in Guanajuato, Jalisco, and Tepic.

C. M. EYE has been appointed superintendent of the American Girl mine, at Ogilby, California. Until further notice his professional address will continue to be at Ocean Park.

H. C. RAY, assistant professor of metallurgy at the University of Pittsburgh, Pennsylvania, is with the Butte & Superior Copper Co. of Butte, Montana, for the summer, in the experimental department.

J. B. LIPPINCOTT announces the opening of engineering offices in the Central building of Los Angeles. With Mr. Lippincott will be associated EDWARD R. BOWEN, who will specialize in steel and concrete structures.

E. T. CORKILL, chief inspector of mines for Ontario, has resigned his position to accept an appointment as safety engineer with the Canadian Copper Co., at Copper Cliff, Ontario. He is succeeded by T. F. SUTHERLAND, assistant inspector of mines.

Obituary

ROBERT PETTIGREW, one of the best known mining men in the state of Washington, died at his home at Roslyn on July 8.

JOHN A. KIRBY, one of the pioneer mining men of Utah and Nevada, died at Providence, Rhode Island, recently. Mr. Kirby was one of the best known mining engineers of the West, having been superintendent of the old Bullion-Beck mine at Eureka, Utah; also of the Daly West mine at Park City and of the Montana-Tonopah at Tonopah. He was one of the original owners of the Nevada Hills property and was one of the directors of this Company at the time of his death.

The Metal Markets

LOCAL METAL PRICES

San Francisco, July 10.

Antimony..... 12-12½c	Quicksilver (flask).....\$41
Electrolytic Copper..... 16-16½c	Tin..... 50-51½c
Pig Lead..... 4.60-5.55c	Spelter..... 7-7½c

EASTERN METAL MARKET.

(By wire from New York.)

NEW YORK, July 10.—Copper is weak and in little demand. Sales reported are of little importance. The greatly decreased stock reported by the Copper Producers' has had no immediate effect upon market conditions. Lead remains unchanged and but little business is being transacted. Spelter continues dull with no change in the market. On July 9, cables from London report copper as easy with spot at £62 10s. and futures £62 15s. Lead is quoted at £15 7s. 6d. and spelter at £20 7s. 6d. The tin market is easy with spot at £177 5s. and futures £178 5s.

QUICKSILVER

The primary market for quicksilver is San Francisco, California, being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

COPPER

Quotations on copper as published in this column represent average wholesale transactions on the New York market and refer to electrolytic copper. Lake copper commands normally from 1-5 to 1-4c. per lb. more. Prices are in cents per pound.

COPPER SURPLUS

Figures showing the visible supply of copper at the beginning of each month are now widely available. Below are given the amounts, in pounds, known to be available at the first of each of certain months. The figures are those of the Copper Producers' Association supplemented by Merion's figures of foreign surplus.

The fortnightly statistics of copper show that the European stocks, including Hamburg and Rotterdam, on June 30 decreased 1727 tons, while copper supplies afloat decreased 50 tons, making a total decrease in the visible supply of 1777 tons to 38,199 tons, as compared with 39,976 tons on June 14 last.

TIN

New York prices control in the American market for tin, since the metal is almost entirely imported. San Francisco quotations average about 5c. per lb. higher. Below are given average monthly New York quotations, in cents per pound:

TIN STATISTICS

Statistics cabled from Europe show decreased visible supplies ranging from 1600 to 1800 tons, according to L. Vogelstein & Co.'s report of July 1. The New York Metal Exchange makes the decrease 2609 tons. The difference is due largely to the exclusion of Europe (other than Holland) from the Exchange figures, all tin going there (which in June amounted to 985 tons) being left out of consideration by the Exchange. It deducts shipments to the Conti-

nent from the total shipments, and the effect is tantamount to enlarging deliveries correspondingly. The net result of the Exchange figures should harmonize closely with foreign statistics, for the former shows supplies, exclusive of Straits' shipments to the Continent, of 4855 tons, and deliveries of 6782 tons, an apparent decrease of 1927 tons in the visible, instead of 2609 tons.

From whatever point of view considered, however, the position is not unfavorable. Doubtless the market would have made a better response were it not for many present uncertainties and the rather dubious future. To date, Straits' shipments are 2000 tons in excess of last year, and those for July are expected to increase this about 1000 tons. Also, while the falling off in American deliveries at the end of June amounted to only 550 tons compared with last year, the decrease at the end of July will amount to about 1500 tons, by which time also the decrease in Europe, now 734 tons, will amount to fully 1000 tons. These increased shipments on the one hand, and decreased deliveries on the other, are having a demoralizing effect, but, price and position considered, much that was unsound in the situation has undoubtedly been discounted.

On June 30 the visible supply was 11,101 tons, having a spot value in London and New York of £193 15s. per ton and 42.625c. per lb., respectively.

COPPER PRODUCERS' ASSOCIATION REPORT

The Copper Producers' Association statement, July 8, shows a decreased surplus. The details are as follows:

		Pounds.
Stock of marketable copper of all kinds on hand at all points in the United States, June 1, 1913	67,474,225	
Production of marketable copper in the United States from all domestic and foreign sources during June	121,860,853	
Deliveries for consumption, June	68,452,572	
Deliveries for export, June	68,067,901	
Stock of marketable copper of all kinds on hand and at all points in the U. S., July 1.....	52,904,606	
Recent changes in surplus have been as follows, in pounds:		
	Increase.	Decrease.
June 1912		5,280,639

Australian Copper Production

The following is from L. Vogelstein & Co.'s copper statistics for 1912:

PRODUCTION OF THE VARIOUS STATES IN TONS

	1911.	1912.
Queensland	20,521	23,157
New South Wales	9,351	8,981
South Australia	6,140	6,505
Tasmania	6,042	5,370
Western Australia	2,473	1,274
Miscellaneous	128	181
	44,655	45,468

PRODUCTION OF THE MOST IMPORTANT MINES IN TONS

	1911.	1912.
Mt. Morgan	7061	8990
Great Cobar	6466	6650
Mt. Elliott	5983	6692
Walleroo	6079	6290
Mt. Lyell	5992	5058

Mt. Lyell's normal production has been over 8000 tons; a strike in 1911 and a fire in the mine in 1912 explain the lower production in these two years. The production of the Wallaroo mine is shipped to Europe as refined ingot copper. Of the remaining production, about 17,500 tons are refined electrolytically in Port Kembla, and the balance is shipped to Europe and the United States in the form of blister, matte, and ores. The estimate of refined copper produced in Australia shows that about 1000 tons remain in the country. England exported to Australia in copper manufactures, excluding brass, 3500 tons in 1911 and 4161 tons in 1912. During recent years a large proportion of the Australian production has been refined in Australia and comes on the European market in the form of electrolytic copper. This enhances appreciably the importance of Australia as a copper-producing country, on the list of which she stands fifth.

Metal Production in Arizona

The total value of the mine output of gold, silver, copper, lead, and zinc in Arizona in 1912, according to V. C. Heikes, of the United States Geological Survey, was \$67,050,784, against \$44,157,223 in 1911. This large increase in value was due mainly to the increase in the production of copper.

The production of gold in Arizona in 1912 was 181,996.90 oz., valued at \$3,762,310, an increase in value of \$331,807. Of this output, 2082.35 oz. came from placers, 112,067.77 oz. from dry or silicious ore, and 57,507.86 oz. from copper ore. From bullion recovered in gold and silver mills, 102,244.72 oz. was produced, concentrate yielded 10,276.48 oz., and crude ore sent to smelters contained 67,086.88 oz. The largest production of gold was from Mohave county—\$1,899,131 in 1912, against \$1,547,663 in 1911.

Arizona's silver production in 1912 was 3,490,387 oz., valued at \$2,146,588, against 3,276,571 oz., valued at \$1,736,583, in 1911. Of this output, 2,378,593 oz. came from copper ore, 373,255 oz. from silicious ore, and 599,110 oz. from lead ore. Bullion produced at gold and silver mills yielded 45,660 oz. of silver in 1912, concentrate produced 387,159 oz., and crude ore sent to smelters contained 2,982,049 oz. Cochise county mines produced 1,962,644 oz. of silver in 1912, against 1,946,319 oz. in 1911, and Yavapai county produced 748,872 oz. in 1912, against 764,744 oz. in 1911.

Copper production increased in Arizona from 306,141,538 lb., valued at \$38,267,692, in 1911, to 365,038,649 lb., valued at \$60,231,377 in 1912. Arizona continued to rank first among the copper-producing states in 1912. Concentrate produced 135,666,375 lb. of the output, and crude ore sent to smelters produced 224,141,378 lb. Cochise county, which includes the great Warren or Blshee district, produced 147,654,661 lb. of copper, against 132,290,007 lb. in 1911. Greenlee county, embracing the Copper Mountain and Greenlee districts of the Clifton-Morenci region, produced 76,848,299 lb. of copper, against 70,926,330 lb. in 1911. Yavapai coun-

ty, including the Verde district, produced 34,043,005 lb. of copper, against 36,103,649 lb. in 1911, and 40,824,556 lb. in 1910. Gila county, including the Globe district, produced 63,969,423 lb. of copper in 1912, against 49,226,341 lb. in 1911. In Pinal and Gila counties the so-called low-grade schist and porphyry ores yielded 76,848,299 lb. of copper, against 30,666,515 lb. in 1911. The copper output of Greenlee county is largely from the same class of deposits.

The production of lead in Arizona in 1912 was 6,806,443 lb., valued at \$306,290, against 10,274,552 lb., valued at \$462,355, in 1911. Cochise county is credited with 3,776,867 lb., valued at \$169,959, the largest part of which was derived from the copper mines in the Warren district. Mohave county followed with 1,937,031 lb. Increased output was made in 1912 from Yavapai county, but there was a decrease in Santa Cruz county. Concentrate yielded 1,731,242 lb. of lead in Arizona in 1912, and 5,075,201 lb. was contained in crude ore sent to smelters.

The spelter production of Arizona was 8,758,243 lb., valued at \$604,319, in 1912, against 4,562,984 lb., valued at \$260,090, in 1911. Mohave county produced mainly from the Union Pass and Chloride camps, 8,304,462 lb. of spelter in 1912, against 4,476,552 lb. in 1911. Productions of zinc were also recorded in Yavapai, Pima, Santa Cruz, and Cochise counties.

There were 444 mines producing gold, silver, copper, lead, or zinc in Arizona in 1912, against 397 in 1911, and the total quantity of ore sold and treated was 6,840,082 short tons, an increase of 2,272,943 tons.

Metal Output of the Central States

The value of the output of silver, copper, lead, and zinc in the states of Arkansas, Kansas, Michigan, Missouri, Oklahoma, Wisconsin, and northern Illinois in 1912 was \$79,675,814, an increase of \$15,156,370 over the value for 1911 and of \$23,349,111 over that for 1908, according to the U. S. Geological Survey. The total value of the production of these metals for the years 1908 to 1912, inclusive, was \$327,385,994, of which \$151,830,008 was for copper, \$98,188,656 for zinc, \$76,217,618 for lead, and \$1,150,512 for silver.

RECEIPTS at the San Francisco Mint in June were as follows:

	Fine oz.
Alaska	9,323.131
Arizona	10,615.523
California	20,182.746
Colorado	1.089
Idaho	37.282
Nevada	3,848.297
New Mexico	297.673
Oregon	335.297
Utah	26.376
Philippine Islands	2,214.697
Washington	5.353
Refineries, Government offices, etc.	177,648.121
Mutilated United States coin	81.390
Foreign coin	9,643.655
Jewelry	849.337
Mexico	70.258
Northwest Territory	7.368

Total receipts 235,187.593
Value of gold, \$4,861,759.03.

The special meeting of the Tuolumne Copper Co. stockholders on August 18, is to increase the stock from 800,000 shares to 1,500,000 shares, par value \$1, to take over the mines of the Butte Main Range Mining Co. in the East Butte district. The promoters are trying to get Pilot Butte to join the combination, and there is also a possibility of the Colusa-Leonard coming in later.

IMPORTS of copper into Russia continue to grow smaller as the domestic production increases. The only copper imported in 1912 was electrolytic, of which the domestic production does not yet come up to requirements.

Philippine Mineral Production

Ore Reserves of Rand Mines

The following statistics of mineral production in the Philippine Islands for the year 1912 have been compiled by the division of mines, Bureau of Science:

The tables compiled by the *South African Mining Journal* classify the ore reserves of the mines according to the various controlling houses or groups, and deal with only

Total value, 3,699,615 Lp., equal to \$17,760,000.		

NEW ZEALAND MINES under the control of the Consolidated Goldfields of New Zealand, at Reef-ton, South Island, produced as follows in May:

	Tons.	Yield.	Profit.	Working costs.
Wealth of Nations.....	1,996	\$16,000	\$5,000	\$3.98
Progress	2,725	10,500	4.32
Blackwater	3,991	36,000	11,000	4.46

At a meeting of directors of the Tuolumne Copper Co. on June 30, it was decided, after a lengthy discussion, to postpone ordering the payment of the quarterly dividend. The Company has only \$50,000 in the treasury. A report presented by the mine's superintendent stated that the company has just opened a fine body of ore on the 2200-ft. level.

Application has been made for the appointment of a receiver for the Butte & Ely Copper Co. A restraining order has also been asked for enjoining the Company from transferring shares of stock held by one Heilbronner to organize the Consolidated Copper Mines Co. A hearing will be given on July 26.

The Consolidated Copper Mines Co. has extended the time for the exchange of the stock of the Giroux Consolidated Mining Co., Butte Ely Copper Co., and the Chain-man Consolidated Copper Co. until July 5. Certificates have been deposited with the Guaranty Trust Co. by noon of July 2.

IMPORTS of chromate and bi-chromate of potash into the United States in 1912, were 32,913 lb. valued at \$3085.

'payable,' fully exposed, and fully valued tonnages, except in one or two special instances. The group aggregates are as follows:

Group.	No. of mines.	Tons.
Central Mining & Investment Corporation	15	38,563,916
Consolidated Gold Fields of S. Africa....	5	8,655,403
East Rand Proprietary Mines.....	1	6,013,000
Anglo-French Exploration Co.....	1	1,687,101
Consolidated Mines Selection.....	1	2,457,000
Randfontein-Langlaagte	2	8,970,639
General Mining & Finance Corporation..	7	6,808,889
Johannesburg Consolidated Invest. Co..	8	6,740,909
S. Neumann & Co.	5	4,268,634
A. Goerz & Co.....	4	2,721,500
Independent Company	1	500,471
	50	87,387,462

THE MT. ROSS mine, New England district, New South Wales, produces tin and diamonds, a peculiar combination. The wash containing tin is sometimes thin, but the dolerite overburden is often 36 in. thick, and contains the diamonds. A six-day run in May resulted in the treatment of 64 loads of wash, yielding 280 lb. black tin, and 201 carats of diamonds worth \$4.80 per carat.

THE following is the gold production of Rhodesian mines in May, 1912:

	Tons.	Value.	Profit.
Eldorado	7633	\$ 88,300	\$ 48,000
Globe & Phoenix	6420	207,000	139,000
Lonely Reef	4900	83,000

DIAMONDS worth \$1475 were mined in the United States in 1912. They are mostly found in Arkansas. The Ozark Diamond Mines Corporation has erected a plant capable of washing 100 'loads' of 16 cu. ft. daily, according to the U. S. Geological Survey.

THE PRINCIPAL GEMS mined in the United States in 1912 were the sapphires from Fergus county, Montana. These were worth about \$195,505, while the value of about 40 various gems and stones, was \$319,722.

CHROMIC-IRON ORE production in the United States during 1912 was 201 long tons valued at \$2753. This came from a mine near Dunsmuir, Siskiyou county, California. Imports were 53,929 tons valued at \$499,818.

COST of mining the deep leads of Victoria, Australia, averages about \$10.35 per fathom of wash. This yields \$16 per fathom at the Great Southern, Rutherglen, and \$11.20 at the Duke Consols, Maryborough.

Company Reports

TRONOH MINES, LTD.

The report of this Company, owning the premier tin mine of the Malay Peninsula, shows that 496,495 cu. yd. of ground was washed, yielding 2776 tons of concentrate, which sold for \$1,680,000. The average yield was 12.5 lb. per cubic yard. During 1911, the output was 3856 tons of concentrate, worth \$2,110,000, the yield per yard being 21 lb. For several reasons, the 1911 output was abnormal. The accounts show a profit of \$758,000, out of which \$576,000 was distributed as dividend, being at the rate of 75%, and \$144,000 was written off the property account. Mr. Griffiths has recommended the adoption of bucket-dredging for a portion of the ground, and A. C. Perkins has confirmed his view. This ground is too irregular in content to be suitable for the present methods used in the richer parts of the Company's property.

LAHAT MINES, LTD.

This Company is nearly allied to the Tronoh, and was formed in 1906 to acquire tin-bearing ground at Lahat, in the Kinta district of Perak, Federated Malay States. The capital is \$576,000, and dividends at the rate of 2½, 10, 15, and 17½% have been paid for the years 1909 to 1912, respectively. The report for 1912 shows that 270,927 cu. yd. of karang was treated, and 441 tons of cassiterite concentrate recovered. This sold for \$264,000, the price received averaging \$6096 per ton. The ground let on tribute brought an income of \$23,000. The mining cost was \$149,000, and after the payment of London expenses and income tax, and allowing for depreciation, a balance of \$115,000 remained. Out of this, \$112,800 was distributed as dividend, being at the rate of 17½%. Additional property has been acquired connecting the old property with the granite hills to the west. O. S. Dawbarn is the manager.

YUKON GOLD COMPANY

The balance sheet of this company, as shown by the report for the year that ended on December 31, 1912, was as follows:

Assets:

Property and investments.....	\$12,026,120.72
Equipment	6,935,801.29
Deferred charges (including stripping)...	441,279.15
Advanced royalties	340,604.44
Supplies and materials	879,292.04
Accounts collectable	502,965.16
Cash	97,350.98
	\$21,223,413.78

Liabilities:

Capital stock	\$17,500,000.00
Guggenheim Exploration Co.....	2,524,972.21
Bills and accounts payable.....	202,272.45
Depreciation	586,893.45
Surplus	409,275.67
	\$21,223,413.78

Details regarding the operations of the year were given June 28. Since the report was issued it has been announced that the Company has leased important dredging grounds on the American river in California and will at once place in operation there a 7½-ft. Bucyrus dredge. This, with the new work at Iditarod, adds materially to the probable profits of the concern.

OURO PRETO GOLD MINES OF BRAZIL, LTD.

This Company was formed by John Taylor & Sons in 1884 to acquire the Passagem gold mine, Minas Geraes, Brazil. Arthur J. Bensusan is superintendent. The report for the year 1912 shows that 68,486 tons of ore was treated, yielding gold worth \$508,000. The working cost was \$432,000, and royalty \$17,700; \$43,000 was allowed for depreciation and \$17,700 was distributed among preference shareholders, being at the rate of 10%. The 100,000 ordi-

nary shares received no dividend; in fact, only \$1 per \$1.80 ordinary share has so far been paid. Labor shortage continues to be one of the troubles at this mine, and efforts are being made to obtain workmen from Europe and elsewhere. Development during the year has not given good results, and the ore reserve has decreased 30,000 tons, and on December 31 were approximately 2½ years' supply. The lode is flat and has hitherto been worked by incline shafts. A main vertical shaft was started two years ago, calculated to cut the lode at 2000 ft. on the dip. Owing to the water troubles, sinking has been delayed.

LONELY REEF GOLD MINING COMPANY, LTD.

This Company has a capital of 325,000 £1 shares, of which 271,007 have been issued, and 53,993 are in reserve. The property consists of 234 claims, water rights, etc., in the Bubi district of Rhodesia, 50 miles north of Bulawayo. The report of the general manager, Francis Drake, covers the year ended December 31, 1912. Mr. Drake, till recently consulting engineer, is now manager, and A. W. Allen is metallurgist.

Development in the mine covered 3701 ft., besides 1459 cu. yd. of stations, winze chambers, and sumps. The main shaft is 1050 ft. deep. Stopping has been done at several points between the No. 2 and No. 7 levels. More ore was broken than was milled, the excess amounting to 11,544 tons, and the total quantity lying in the stopes at the end of the year was calculated to be 13,074 tons. Almost all of this is in shrinkage stopes, which are the most economical to work in certain portions of the mine. Another advantage of this method of stopping is that the mine is independent of fluctuations in the supply of native labor. Two additional levels, the eighth and the ninth, were opened during the year at depths of 895 and 1020 ft., respectively. On No. 8 level, 626 ft. was driven, of which 604 ft. was in ore; and 398 ft. was driven on No. 9 level, of which 166 ft. was in ore. These levels have not yet been extended to the full length of the ore-shoot, and driving is being continued in pay-ore. Shaft-sinking was suspended toward the end of the year, owing to the fact that the ore-shoot showed signs of trending again to the south, as it does in the upper levels of the mine. To determine this trend, a winze has been sunk from No. 9 level. This is now down 104 ft. in rich ore, without having reached the northern limit of the ore-shoot. The length sampled in this winze is 73 ft. Of this, the first 23 ft. averages 12.16 dwt. over 48.83 in., the next 25 ft. averages 29.31 dwt. over 50.25 in., and the last 25 ft. averages 37.36 dwt. over 36.8 in., the reef not having been fully exposed in places. This winze is the deepest point yet reached in the mine, being now 1124 ft. from the surface. Arrangements have now been made for the sinking of an incline shaft below the No. 9 level for the development of the deep ground in the mine. The new hoisting station and ore-bins for this inclined shaft are being prepared, and sinking will be started as soon as possible. The additional plant required for the purpose has been ordered.

The ore reserves at December 31 last were estimated at 174,529 tons, of an average assay value of 22.40 dwt. They show an increase, after deducting the 37,655 tons sent to the mill, of 24,185 tons compared with the estimate of 140,344 tons at December 31, 1911. The present reserves represent approximately a 3½ years' supply of ore for the reduction plant, calculated on a working capacity of 4000 tons per month. The average assay value of the reserves is slightly less than that shown in the previous year, owing to the inclusion of some blocks of lower-grade ore at the southern end of the ore-shoot. The results of operations were as follows:

Ore treated, tons	37,655
Old slime treated, tons	6,331
Total gold production	\$768,000
Mining, milling, treatment, etc.	245,000
General, office, directors, taxes, etc.	139,000
Profit	384,000
Dividends paid	259,000
Capital expenditure, development, equipment.....	134,000

Book Reviews

COLORADO GEOLOGICAL SURVEY, BULLETIN No. 6. By R. D. George. P. 406. Maps, diagrams, index.

The main purpose of the bulletin is to describe the commoner minerals and rocks, and furnish the means of recognizing them and of knowing their use. Many valuable geological materials lie unused for lack of knowledge of what they are and how they may be used. It is hoped that this work may stimulate an interest in and a search for the valuable geological products. In this book the author has endeavored to present a handbook of rocks in a form which will be comprehended by everyone interested in the important facts regarding the materials of geology. Emphasis has been given to the important minerals and rocks, unimportant species being described only where their intimate relationship to the more important types has made it necessary, or where the possibilities of economic uses have made it desirable. The work includes a discourse on crystallography, showing with illustrations the various crystal forms as found in nature. It also discusses cleavage, fracture, hardness, specific gravity, color, lustre, streak, and other physical features by which the various minerals may be recognized. It then describes in detail the rock-making minerals, non-metallic minerals, gem minerals, and the metallic minerals, giving the various characteristics of each and the method by which they may be recognized. The characteristic reactions of the important elements are given. The common rocks are described under the heads of igneous and sedimentary, and the subject of metamorphism and the metamorphic rocks is also included. Building stones, the materials of cements, limes, and plasters are also covered by this work. A glossary of geological terms is included.

THE MEN WHO BLAZE THE TRAIL. By S. C. Dunham. P. 126. Barse & Hopkins, New York.

This little book of verse is one of the charming by-products of mining in the Far North. In it Mr. Dunham voices the thoughts and feelings of the Alaska 'sour-dough' as Mr. Service has done for his brothers in the Yukon. The modest little volume is intensely photographic; the verses are word pictures of things as they are, or at least as they were in the early years at Nome. Incidentally, Mr. Dunham has phrased, and excellently, the feeling of helplessness and hopelessness that has come to the sturdy, self-reliant pioneers of the North who face new conditions that they neither approve nor understand. Thus:

"We're too slow for the new breed of miners,
Embracing all classes of men,
Who locate by power of attorney
And prospect their claims with a pen—
Who do all of their fine work through agents,
And loaf around town with the sports,
On intimate terms with the lawyers,
On similar terms with the courts."

Mr. Dunham has caught the brooding spirit of the North, but he also knows the desert, and his later poems, in which he depicts life in Nevada, are equally interesting. Thus he sums up the campaign of 'Lem Allen of Churchill' for the position of lieutenant-governor in 1903:

"And if Lem keeps on talking and treating
In the extra dry way he's begun,
He will turn down the traitors to Silver
By a ratio of sixteen to one."

PSYCHOLOGY AND INDUSTRIAL EFFICIENCY. By Hugo Münsterberg. Pp. 321. Index. Houghton, Mifflin Co., Boston. For sale by the *Mining and Scientific Press*. Price \$1.50, postpaid.

Some one has said that lately no publisher has considered his list complete unless it contained at least one book upon scientific management or efficiency engineering. That may be only another way of saying that far too many books have been written upon this new but really important science. The book under review does not come under

the heading of those which were written as a sop to the vanity of the author or as an advertisement of his professional qualifications. It is, on the other hand, a real contribution to the science, and one that will go a long way toward clearing up much of the general distrust of so-called scientific management methods. It is written in a simple and readable style, free from unusual technical terms. After a general introduction on 'Applied Psychology,' the author discusses 'The Best Possible Man,' 'The Best Work,' and 'The Best Possible Effect.' A few of the chapter headings, selected at random, will give a good general idea of the contents: Vocation and Fitness. Scientific Vocational Guidance. Experiments in the Interest of Electric Railway Service. The Adjustment of Technical to Psychological Conditions. The Economy of Movement. Experiments on the Effects of Advertisements. Buying and Selling. The Future Development of Economic Psychology.

"The book has a message for everyone interested in either industrial or human efficiency, even though its human efficiency message may chiefly concern one's own self."

POTASH SALTS, SUMMARY FOR 1912. Compiled by W. C. Phalen. Advance chapter from 'Mineral Resources of the United States, 1912.' U. S. Geological Survey. P. 36. Mr. Phalen has brought together in this little pamphlet, not only the statistics of consumption and imports, but such data as are available bearing on the problem of possible local production. He has given a brief summary of the investigations now being conducted by the U. S. Geological Survey and the Bureau of Soils, and indicates several promising fields. Mr. Gale's statement regarding the Seales lake deposits is quoted elsewhere. In it important data supplementary to the brief announcements made by the Survey last year are published.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

IDLE RAILWAY CARS in the United States in May totaled 50,294. There were 10,000 new cars bought during the month.

CONCENTRATION of 390,473 tons of ore, by 14 mills, at Cobalt during 1912, resulted in 10,527 tons of concentrate, a ratio of 37 to 1.

STANDARD rack and pinion ore-bin gates are of the following sizes: 18 by 24, 20 by 28, 24 by 30, and 30 by 36 in., with their respective weights of 225, 250, 275, and 325 pounds.

SHIPPING through the Suez canal in 1912 totaled 5373 ships of 20,275,120 net tons. Receipts were \$27,005,068, and dividends paid \$16,847,540. This should be something to compare with the Panama canal when in full operation.

HORSE-POWER of turbines on the German steamer *Imperator*, the largest in the world, totals 60,000 hp. Her dimensions are: length, 919 ft., and beam, 98 ft., 9 decks above water-line, 36 water-tight compartments, and 50,000 tons.

'TIMBERING' in the main shaft of the Lonely Reef mine, Rhodesia, has been done with wood to 795-ft. depth, and with steel sets the remaining 255 ft. Although more expensive in first cost than the wooden timbers, the steel is practically indestructible.

CRUSHING EQUIPMENT at the Miami mill, Arizona, is being increased by the installation of two sets of 16 by 42-in. Miami heavy-type rolls of Traylor make, and two sets of screens. This increase of plant will produce ½-in. size of ore for further treatment.

TREATMENT of the Lonely Reef mine, Rhodesia, consists of twenty 1250-lb. stamps each; two tube-mills 5 by 14 ft., and one 5½ by 16 ft.; four 20-ft. diam. Dorr thickeners; four 8 by 32-ft. Pachuca agitators; and three Dehne filter-presses, with 50 chambers 40 in. square.

GOLD AND SILVER EXPORTS from New York from January 1 to June 21, 1913, totaled gold, \$60,179,782, and silver, \$25,016,845, against \$22,483,762 and \$24,984,679, respectively, in 1912. Imports totaled gold, \$8,516,135, and silver, \$4,450,675, against \$10,248,474 and \$5,245,674 in 1912.

TORIN BRONZE is a composition containing between 59 and 63% copper, 0.5 and 1.5% tin, and a small percentage of zinc. It has a bright golden color, specific gravity of 8.4, melting point of 1600°F., weighs 0.303 lb. per cubic inch, and can be welded by electric or oxy-acetylene processes.

DIAMOND-CUTTING is mostly done in Europe, at Amsterdam and Antwerp, 23,000 persons being engaged in the industry, and the cost being about \$24,000,000 per year. It is now proposed to do a lot of this work in South Africa, which, last year, exported uncut diamonds worth \$57,600,000.

MINING COSTS at the Calumet & Hecla properties during 1912 were as follows, according to the *Houghton Mining Gazette*: Ahmeek, \$1.39; Allouez, \$1.61; Calumet & Hecla, \$1.91; Centennial, \$1.92; Isle Royale, \$1.54; Osceola, \$1.23; Superior, \$2.23; and Tamarack, \$2.23; an average of \$1.77 per ton.

TREATMENT of mixed sand and slime, or slime alone, by upward displacement is attracting some attention in the United States, and good results are said to have been secured. There are difficulties in getting uniform results, and everything must be in extremely nice adjustment. Upward displacement was tried at the Westralia Mt. Morgan's mill, and a slime plant at Kalgoorlie for treating old dumps, several years ago, but results were hopeless.

IN AGITATING SLIME with barren solution, it is difficult in many cases to find an ore which will allow sufficient decantation to take place to furnish enough solution for agitation purposes. On clayey ores the upward current of the solution through the decanting zone carries slime particles with it in every case, and under all conditions.

UNCONSUMED GASES in boiler flues are liable to cause explosions. Recently, at a mine in Western Australia, a boiler fireman shut the damper down and stopped the fan to 'blow down' the boiler. After doing this, he opened the damper, and flames from the wood fuel exploded the accumulated unconsumed gases, blowing out a quantity of brickwork.

THE flame blow-in of a Case gasoline melting furnace is placed so that the flame enters the furnace on a tangent and does not hit the crucible until there is complete combustion. The hot gases circle around the crucible, thereby preventing the loss of crucibles by cracking, and saving their wear and tear to such an extent that their life is lengthened several melts. This furnace is made in three sections, or practically divides in the centre, so when the upper ring is lifted off it leaves the upper portion of the crucible so exposed that it can be removed with basket tongs.

RAILROAD TUNNELS through the European Alps are the Mont Cenis, St. Gothard, Arlberg, Simplon, and Lötschberg. The latter is about 9¼ miles long, the St. Gothard 9½ miles, and the Simplon 12¼ miles. After nearly two years' work in the Lötschberg 'headings', an accident occurred. It was supposed by the engineers that the detritus forming the floor of the Gastern valley ended well above the line of the tunnel, which in consequence would be driven in solid rock. This supposition was wrong, as there was a rush of sand, gravel, and water, amounting to 250,000 cu. ft., filling the heading for nearly a mile and killing 25 Italian miners. Later on, a new heading was started, and work was completed on March 31, 1911.

CLEAN-UP BARRELS, as used at Kalgoorlie for treating the amalgam, rich concentrate, and chippings from grinding pans, or sundry material from the clean-up room, are simply of cast iron, 2 in. thick, with a 3-in. shaft fitted through the centre and extending outside for bearings and driving gear. They are best driven by gearing at about 20 r.p.m. One side of the barrel has a heavy door about 10 by 18 in., well fitted in a hole, and is clamped down. The machine is charged with the material to be ground, enough water added to make a thick pulp, and enough quicksilver to collect all gold and amalgam. Lime or soda is added to clean the mercury. About four rollers, say 4 by 12 in., are also added for grinding, which occupies about 12 hours. After this time, the barrel is opened, the pulp run into a box or vat, thinned with water, and then run over riffles. The residue is rich and is caught in a box, and returned to the pans. The barrel does good work and may be securely locked.

QUICKSILVER occurs in nature principally as sulphide, namely, cinnabar. The deposits in the United States are found generally in simple fissure fillings, frequently irregular and linking together larger fillings; in compound fracture zones; along bedding planes or other contacts; and disseminated in the adjoining rocks. The ore-shoots are often very irregular and sometimes lenticular. They are found in many kinds of igneous, sedimentary, and metamorphic rocks of various ages, such as granitic, quartz porphyritic, rhyolitic, andesitic, diabasic, and basaltic igneous rocks, limestones, sandstones, shales, serpentines, slates, and quartzites. Cinnabar, the principal ore, has a formula of HgS, and contains up to 86.2% mercury. It has a beautiful red color, and is found in crystalline incrustations, intergrowths, and impregnations, also granular, massive, and earthy. Its hardness is 2 to 2½, and specific gravity 8 to 8.2. When scratched, it gives a scarlet streak. The ordinary variety is crystallized, massive, and earthy, and bright red to reddish brown in color.

High-Voltage Direct-Current Locomotives

The electrification of the Butte, Anaconda & Pacific railway is of exceptional interest because it represents one of the largest installations of electrical equipment for steam railroad service and is the first in this country where direct-current locomotives, operating on as high a potential as 2400 volts, will be employed. Construction work necessary to effect the change from steam to electric equipment is now practically completed.

The adoption of the 2400-volt, direct-current system for this railway was determined after a comprehensive study of local conditions and requirements. The traffic demands are unusually severe, and consist principally of hauling long trains of copper ore over heavy mountain grades. In comparison with other existing systems, the 2400-volt, direct-current system was considered best suited for exacting service of this character; for its adoption presented

tained. The average train is composed of a locomotive and three standard steam-road passenger coaches. All the locomotive equipment, as well as the sub-station apparatus and overhead line material, was designed and built by the General Electric Company.

The principal data and dimensions applying to the locomotives are the following:

Length inside of knuckles	37 ft. 4 in.
Length over cab	31 ft.
Height over cab	12 ft. 10 in.
Height with trolley down	15 ft. 6 in.
Width over all	10 ft.
Total wheel base	26 ft.
Rigid wheel base	8 ft. 8 in.
Track gage	4 ft. 8½ in.
Total weight	160,000 lb.
Weight per axle	40,000 lb.
Wheels, steel tired	46 in.
Journals	6 by 13 in.

DIRECT-CURRENT LOCOMOTIVE, 2400-VOLT.

an opportunity to realize unusual economies, both in initial expenditure and the cost of operation.

The part of the road that has been equipped lies between Butte and Anaconda, Montana. It comprises 30 miles of main line single track, numerous sidings, yards, and smelter tracks, aggregating a total of about 90 miles on a single track basis. The haulage of copper ore from the Butte mines to the smelters at Anaconda, together with all mine supplies, lumber, etc., moving in both directions, amounts to practically 5,000,000 tons of freight per year. Complete freight trains weighing 3400 tons are made up of 50 loaded steel ore-cars and will be operated over a ruling grade of 0.3% by a locomotive consisting of two of the units illustrated. Single units will be used for making up trains in the yards and for spotting cars.

The initial equipment consists of seventeen locomotive units, type 0440-E-160-4 GE 229A; fifteen for freight and two for passenger service. Each unit weighs approximately 80 tons. The two units for forming the freight locomotives in each case will be coupled together and operated in multiple unit. The combination freight locomotives will haul the usual trains of 3400 tons at a maximum speed of 15 miles per hour against the ruling grade, and at 21 miles per hour on level tangent track. The passenger locomotives are the same design as the freight locomotives, except that they are geared for a maximum speed of 45 miles per hour on level tangent track. A schedule of eight passenger trains per day, four each way, is main-

Gears, forged rims, freight locomotives.....	87 teeth
Gears, forged rims, passenger locomotives..	80 teeth
Pinions, forged, freight locomotives.....	18 teeth
Pinions, forged, passenger locomotives.....	25 teeth
Traction effort at 30% coefficient	48,000 lb.
Traction effort at one hour rating	30,000 lb.
Traction effort at continuous rating	25,000 lb.

The locomotives are the articulated double-truck type, with all weight on the drivers. The cab, containing an engineer's compartment in each end, and a central compartment for the control apparatus, is carried by the two truck frames on centre pins. The cab is box type, extending the entire length of the locomotive, and is provided with end and side doors. On each axle is mounted a motor of the twin-geared type. The friction draft gear mounted on the outer end frame of each truck transmits the hauling and buffing stresses directly through the truck frame, diverting these strains from the centre pins and underframe.

The trucks are built of heavy steel castings. The side frames are of a truss pattern with heavy top and bottom members and pedestal tie bars. They are connected by end frames and a cast steel centre transom. The entire weight is carried on semi-elliptic springs suitably equalized. The cab underframe consists of two 12-in. longitudinal steel channels on either side of the centre and two 6 by 6-in. steel angles along the outer edges. The central channels are enclosed and form a distributing air-duct

for forced ventilation. Air is conducted through the centre pins, which are hollow, into the truck transoms and thence to the motors.

The engineer's compartment, at either end of the cab, contains the operator's seat, controller, air-brake valves, bell and whistle ropes, ammeter, air gauges, sanders, and other control apparatus that should be within immediate reach of the engineer. These compartments are comfortably heated by electric heaters. In the central section is grouped the control apparatus. The contactors, reverser, and rheostats are mounted in two banks running lengthwise of the compartment, and are arranged with ample space between them to afford convenient access for cleaning, inspection, and repair. All parts and circuits carrying 2400 volts are thoroughly protected from accidental contact. A dynamotor is employed to furnish 600 volts for the operation of the contactors, lights, and air-compressor.

The motors are the GE-229A commutating-pole type, wound for 1200 volts and insulated for 2400 volts. A forged pinion is mounted on each end of the armature shaft and meshes into a corresponding gear mounted on the wheel hub. The gear reduction is 4.84 on the freight locomotives and 3.2 on the passenger locomotives.

The GE-229A motor is designed especially for locomotive service, is enclosed, and is provided with forced ventilation. Air is circulated over the armature and field coils, over and through the commutator, through longitudinal holes in the armature core, and thence exhausted through openings in the bearing head. This method of ventilation circulates effectively a large volume of cool air throughout the motor and keeps all parts at a uniform temperature, eliminating the possibility of 'hot spots.'

The continuous capacity of each motor is 190 amperes on 1200 volts under forced ventilation, and 225 amperes on 1200 volts for the one-hour rating. For the double unit 160-ton locomotive, this is equivalent to a continuously sustained output of 2100 horse-power.

The control equipment on the locomotive is the well known Sprague-General Electric, type M, multiple-unit control, and is designed to operate the four motors in series and series-parallel. The pairs of motors with their respective resistances are all connected in series on the first point of the controller. The resistance is varied through nine points on the controller and finally short-circuited on the tenth or running point. The pairs of motors are then operated similarly in series-parallel and all resistance is cut out on the nineteenth point, which is the full-speed running point. This provides a control with ten steps in series and nine steps in series-parallel.

The transition between series and series-parallel is effected without opening the motor circuit, and there is no appreciable reduction in tractive effort during the change. The smooth transition between control points permits acceleration close to the slipping point of the wheels. A switch is provided having manually-operated handles for cutting out either part of motors, so that the locomotive can then be operated with one pair of motors in the usual way.

The contactors are actuated by the 600-volt circuit obtained from the dynamotor and are of a design similar to that employed in the standard type M control. The principal variations are embodied in the method of insulating for the higher voltage. The arm between the operating armature magnet and the arc chute mechanism consists of a treated wood spacer insulator; and the contacts and magnetic blow-out, which make and break on the 2400-volt circuit, are mounted on mica and porcelain insulators.

The main switch is provided with a powerful blow-out, so that heavy currents can be opened. The three smaller switches, one for each of the two heaters and one for the dynamotor circuits, are designed specially for 2400 volts. The blade is controlled by a lever attached to the grounded part of the locomotive frame and insulated from the live parts of the switch by a rod of treated wood.

There is one main fuse for the trolley circuit and two fuses for the motor circuits. They are all of the copper ribbon type and are fitted with hinged covers to facilitate fuse renewals. The boxes are placed as near as possible

to the overhead trolley in order to protect the wiring circuits near the source of supply. There is also an auxiliary circuit fuse for protecting locally the dynamotor and heater circuits. The main, motor, and auxiliary fuse boxes are provided with powerful magnetic blow-outs, energized by current passing through the fuse, to insure proper rupture of the arc.

An ammeter is placed at each engineer's position and indicates the current in the circuit of one pair of motors. The ammeter and air-gauges are illuminated by a gauge light connected in the headlight circuit, so that the headlight switch turns on simultaneously the headlight and gauge light at the same end of the locomotive.

The main motor rheostats are formed of cast-iron grids assembled in a frame and insulated by mica. Twenty resistance units are provided for each passenger locomotive, and twenty-six resistance units for each freight unit. The rheostat boxes are mounted in an enclosed compartment, above the banks of contactors.

Current is collected by overhead trolleys of the pantograph type. They are pneumatically operated and can be put into service from either engineer's compartment by a hand-operated valve. Each passenger locomotive is equipped with two collectors, and each freight unit with one collector. A 2400-volt insulated bus line, connected direct to the pantographs, is run along the centre on the roof of the cab. The bus lines are connected by couplers between the two units of the freight locomotives, so that current is obtained from both collectors or from a single collector. The collectors and bus lines are adequately guarded by railings.

The locomotives are equipped with arc headlights. The interior illumination of the cab is provided by ten incandescent lamps arranged in two circuits, one lamp being placed in each engineer's cab and the balance in the central compartment. In each lamp circuit is a portable lamp with an extension cord. One lamp switch is in each engineer's cab, so that one lamp circuit can be controlled from each end of the locomotive. A 600-volt bus line is provided on the passenger locomotives for lighting and a 2400-volt bus line for heating the passenger coaches.

The air-brakes are the combined straight and automatic type. The air-compressor, of the CP-26 type, is two-stage, motor-driven, and has a piston displacement of 100 cu. ft. of air per minute when pumping against a tank pressure of 135 lb. per square inch. Air is taken from the interior of the central compartment through a screen, which prevents the entrance of particles of dust. The compressed air in passing from the low-pressure to the high-pressure cylinder is conducted through radiating pipes on the roof of the cab. This reduces the temperature of the air and allows condensation of moisture before entering the high-pressure cylinder. From the high-pressure cylinder it is delivered into four air-reservoirs, each 12 by 164 in. They are placed under the floor of the cab and connected in series, which affords a further opportunity for radiation and condensation.

Pneumatic sanders are provided. The sander valves are placed within convenient reach of the engineer's seat, and valves and boxes are arranged for sanding the track in front of the leading wheels when running in either direction. The couplers are M.C.B. standard. The bells are fitted with automatic bell ringers, and the whistles are air-operated. All wiring is drawn through conduits and carefully protected from possible mechanical injury.

HUMPHREY PUMPS, as described in this journal of June 28, will lift water the same as an ordinary pump by suction and deliver to heads up to 250 ft. They will operate on kerosene, distillate, gasoline, benzol, or any form of gas available.

H. N. LAWRIE has opened an office in the Yeon building at Portland, Oregon, for microscopic study of ores and rocks and for general mining engineering work.

COKE production of the United States averages about 400,000 tons per week.

DUMMY directors will have a hard time of it in the future, if the ruling made by the Supreme Court of New York State holds good. A shareholder in White, Van Glahn & Company sued Mr. H. K. White, alleging that Mr. White, though knowing the company to be insolvent, became a director (thereby facilitating the sale of stock through his reputation for wealth and business success), but allowed the affairs of the Company to be managed by others, with the result that a few months later it became bankrupt. The opinion of the court, concurred in by all the justices, was that Mr. White was liable for the \$50,000 lost by the shareholder who invested in the Company under the belief that it was being actively managed by Mr. White. This is a new ruling, but one that seems eminently sound. It is all too common that well known men allow their names to be used as bait to catch the unwary, and it is to be hoped that the establishing of legal responsibility for losses may act as an effective deterrent. All too often, however, those who are so unwise have little beyond their reputations to lose in the ensuing maelstrom.

SPECIAL CORRESPONDENCE is one of the departments of the *Mining and Scientific Press* that is distinctive in tone. In the course of a year we print more than 300 letters written from various corners of the world. In part these are from regular members of the staff, in part they are from resident engineers, and frequently they are the friendly comment of visitors. They all contain much technical information, and they afford the reader an easy medium for keeping in touch. Mr. Edward Walker's letters from London have contained, among other things, the best chronicle of the development of flotation, as well as detailed news of British controlled properties throughout the mining world. In the current issue the expansion in operations which is being undertaken by the St. John del Rey company is recorded, and the progress which is being made by the Institution of Mining and Metallurgy. The account of the Tonopah-Continental controversy by an engineer on the ground is of particular interest, and furnishes a side-light on the situation by a disinterested party. In our correspondence with consulting engineers are presented the views and opinions of experienced operators on the districts visited. Such comment enables the people of the community to realize Burns' ambition "to see oursel's as ithers see us," at the same time that they give valuable information to outsiders.

THE great mineral wealth of South America, which has been known since the days of the Incas, has up to the present time been lagging in development, due to a combination of circumstances largely exterior to the country itself, coupled with obstacles which nature has placed in the path of the prospector and the difficulty of access for materials and supplies. If the investing public awoke to the realization that there are large mineral tracts on the eastern slope of the Andes, and that a country, rich in gold, silver, copper, zinc, mica, tin, and all kinds of mineral products, is only awaiting the advent of capital to develop this territory into dividend-paying investments, the progress would be a great deal faster. To the average mining investor, South America is an almost total void in the field of possible investment, and the country is looked upon as an unknown quantity outside of the large copper companies of Chile and Peru, the emerald mines of Colombia, the diamonds of Brazil, and the tin deposits of Bolivia. In reality, the country presents an almost virgin field for future exploitation which is not surpassed anywhere. The principal difficulty, as in all new countries, has been the lack of transportation facilities and means of access into the distant parts in which the mines are to be found. While the actual existence and situation of ground, which would be valuable under ordinary circumstances, is known, the fact remains that with the heavy transportation charges, they are impossible enterprises under present conditions. However, we are pleased to note that at the present time there is an awakening taking place as to the mineral possibilities of that continent, and an increased activity in railway construction is taking

place in many quarters. The extension of railroad lines and the solution of Bolivia's transportation problems is discussed in the present issue by Mr. G. W. Wepfer.

RAILWAY construction in Alaska by the federal government is provided for by the Jones-Chamberlain bill, which has been reported favorably to the Senate and is now being considered by the Committee on Territories of the House of Representatives. The bill provides for the issuing of \$40,000,000 worth of 3 per cent government bonds, and authorizes the President to utilize these funds for the construction of railways in Alaska, using his discretion as to routes, and employing the Panama canal engineering force, army officers, or a railway commission to carry on construction work. Messrs. Falcon Joslin and M. D. Leehey have appeared before the Committee as advocates of this bill, which seems an excellent one. It is interesting in this connection to note that the report of the committee which investigated the recent wreck on the New York, New Haven & Hartford railroad intimates that a closer supervision of railroads by federal authorities may soon prove necessary in the interests of public safety. Railway managers in some cases are apparently approaching a state of affairs where they may be glad to resign themselves into governmental hands, for in the face of constantly increasing operating costs resulting from demands for higher wages by operators, and of decreasing income through higher taxation and an inability to raise freight rates, the lot of a "railroad magnate" would not appear to be an entirely enviable one.

INSPECTION is a recognized method of increasing efficiency and safety, and many of the larger companies employ regular mine inspectors who have no other duties than those implied by their title. The Arizona Copper Company, Limited, has just organized an inspection department and placed it in charge of Mr. Frank Farmer. Coal operators in some of the states have organized mutual insurance companies and found that the value of the inspection alone offsets the cost of the insurance. In mining, as in other industries where much work is done by relatively unskilled labor, a generous number of well trained and well paid inspectors, free from the burden of routine management, are profitable. This is especially important where men of different nationalities work together and there is no common language. The danger from lack of a common tongue is so great that in many states efforts are being made to forbid employment of men underground who cannot speak and understand English. Such a rule, if general, would promote safety, but would also cripple industry. Dropping theories and facing conditions, employment of competent instructor-inspectors seems to best meet the existing situation. While a certain number of accidents and lives lost annually is unavoidable in the operation of mines, that this figure can be materially decreased by a concerted effort on the part of the operators is equally true. It is hoped that the example which is being set by some of the large operators will become more general.

Colloids and Their Importance

Those ancient Greeks who spent their time chiefly in the inquiry for some new thing are usually regarded as dilettantes, yet such a habit of mind has much to commend it. More especially is this true if eagerness to learn something new is coupled with a practical ability to turn it to service, for of such a fibre are the men chosen by nature to become leaders in industry and art. The engineer whose work causes him to move frequently from place to place, quickly comes to regard an abundance of material possessions as a doubtful advantage; Morris chairs and grand pianos have their advantages, but their drawbacks as well. Similarly, it may be said that too much knowledge has its disadvantages. A few centuries ago, when nobody knew very much, it was comparatively easy for any intelligent man to keep in touch with all that happened in his little world. Nowadays the events of the universe are served to us with our breakfasts, and unless we are energetic enough to arise early for the purpose, most of us can scan them but hastily if we expect to punch the time-clock on schedule. Even the newspapers themselves feel the pressure, and the progress of any matter is abandoned as soon as it ceases to be exciting. Thus the cables tell of rioting Rand miners, but nothing of the resumption of work; of the looting of a smelter in Mexico, but nothing of monthly output. But especially in the world of scientific work is this difficulty felt. Workers in every possible field of those sciences which are based on physics and chemistry are daily discovering something new, or putting old relations in new lights, and the task of anyone so rash as to attempt to cover the whole field is clearly beyond human powers. The problem of the average man thus becomes the distinguishing of what is most important out of the mass of material which is readily available to him. It may be truthfully said that such a critical review of the world is the task of the editor, but he is but one man and can only present that which he conceives as most important to the average man. The need of any given individual may vary markedly from the average, so that each must perforce either devote his own effort to the task, or else be satisfied with the outcome of fortune which may place in his way that which he needs, or lead him by other paths.

Perhaps the best instance of our argument is the profound research work upon colloids which has been done, chiefly in the past two decades, in this country, but more especially in Germany. Those who were trained in the earlier concepts of physics and chemistry were taught to recognize three states of matter, solid, liquid, and gaseous. Though it was recognized that some substances did not exactly fit in such a classification, little attention was paid them, because further work was needed to bring about the recognition of their importance. Chiefly as a result of the persistent labors of those botanists who were insistent upon learning how and why the sap can rise to the topmost twig of a tall tree, we have come to know that solids dissolved in liquids cease to exhibit many of the character-

istics of solids and take on new and astonishing properties which serve to explain many puzzling problems. Also, we have learned that there are substances which seem to lie on the border line between solids and liquids; these have been called colloids. A solid dissolved in a liquid can be made to pass through parchment; a colloid can not, though frequently indistinguishable to the eye from a true solution. Glue, gelatin, and gum arabic are common examples of colloids. The importance of the colloid state depends, however, on the comparatively recent discovery that by using proper methods almost every substance can be caused to assume the colloid state. Thus colloid solutions of gold, silver, and other metals can be prepared which exhibit properties markedly different from the solid and liquid forms of the true substance. Careful study with the ultra-microscope and in other ways has disclosed the fact that the particles composing colloid substances are smaller than the wave length of light, but larger than molecules, and exhibit peculiar motions.

Of the many interesting and peculiar properties of colloids, we cannot speak at length from considerations of space. A few instances of their practical importance to mining men must suffice. Comminution is one of the methods by which ordinary substances can be made to assume the colloidal state. Thus in grinding ore in the process of ore dressing, a certain amount of colloid may be formed, according to the method employed. The millman vaguely covers this in saying that grinding should be done so as to yield a granular product rather than a 'slime.' 'Slime' is hard to treat because it consists, in part at least, of colloidal material, and the methods adapted to the treatment of solid particles are but poorly fitted to deal with colloids. The valuable mineral may be reduced to the colloid form, and so lost, or the discrete particles of mineral may be entangled in the colloid, like sand in glue, and so escape. In hydro-metallurgy the importance of colloids is even more marked. Cyanide metallurgists have devoted much study to this problem, and in this field the influence of colloids is better recognized. Here again the difficulty is twofold: the colloid material mechanically interferes with the operation of filtering devices, and it also holds within itself some dissolved substance which no degree of washing will completely remove. This is because of a peculiar property of colloids, known as adsorption, which enables them to take dissolved substances out of solution and retain them with the greatest tenacity. Fortunately the colloids formed in grinding ordinary gold ores exhibit no marked selective tendency to adsorb the double cyanide of gold and potassium, so this influence, though perceptible, is not troublesome. It is not at all improbable that this property will be marked in the fine grinding and leaching of copper ores, and we venture to prophesy that investigators in the hydro-metallurgy of copper will find it necessary to carefully consider this influence which colloids may have upon their work. Finally, it is not at all improbable that colloids as well as the phenomena of surface tension are important in mineral flotation.

Underestimating the Cost of Milling Plants—I

By A. SYDNEY ADDITON

Among the remarks commonly heard when several persons are discussing some new milling plant are: "I guess it is a good plant, but it cost about twice what they expected it to cost," "Yes, the plant is finished, but they will have to spend a lot more money on it before it is efficient," "Plants always cost twice what they are estimated to cost." Or at a directors' meeting, when a contemplated structure is under discussion and an estimate has been submitted, some one will say: "Add 75% to that amount and you will come close to the actual cost, is my experience."

Causes of Underestimating

Why is this and why are such ideas prevalent? Often, of course, persons making such remarks are speaking without knowledge, but too often the observations are true. Why should it ever happen that a plant estimated to cost \$100,000 should cost \$150,000? Misrepresentation, bad management, incompetency, ignorance, lack of technical advice, crooked business, and graft, are given as the reasons, and some or all of these may be assumed to cover the case. What is meant by such reasons, and how each of them acts to the end, is not as a rule clearly understood, as they are given off-hand, with but seldom any inquiry beyond. They are general reasons and, as general reasons, are largely true. They would be reasons for failure in any business enterprise. Exactly what happens to cause the cost of a given structure to exceed original estimate is not commonly clear.

For elucidating this point and supplying data which may aid engineers and managers to escape falling into the clutches of the underestimated cost bugaboo, I have studied the matter in considerable detail, and some of the results of this investigation follow. The discussion is confined wholly to mills and milling operations, and it is assumed that the mine work in each case is satisfactory and in no way affects the topic under discussion. At one property I visited, a new stamp-mill and cyanide plant had recently been constructed and were running smoothly and giving satisfactory results. The arrangement of certain parts of the equipment being peculiar and differing from the usual practice, led me to inquire the reason. This question brought out the history of the construction of this plant, which had cost 41% more than the original estimate submitted to the directors of the company at the time they voted to build. This history, while by no means unusual, throws much light on our inquiry.

History of One Undertaking

To begin at the beginning, this property was owned by a group of clever, conservative, well-to-do business and professional men, all of whom believed in doing well and thoroughly everything they undertook to do. They all realized that it cost money to develop and equip a mine, and were ready

to meet contingencies. They were the right sort; men for whom an engineer or other employee would do his best. They had purchased the property in an undeveloped state, and immediately started to find a competent reliable man to develop it for them either into a producing mine or to the point of abandoning the venture. They took their time in making a selection of the engineer, realizing the importance of this first step, and finally succeeded in securing the services of just the man needed. This done, they supplied the funds and told him that it was up to him to make a mine or advise them to quit. He had their entire confidence and was given a free hand.

Under these favorable conditions the development of the property was rapid, the vein was well opened and ore found to be of workable grade was blocked as fast as developed. The superintendent cautioned the company against thinking of a milling plant too soon. But after a couple of seasons of this well directed development, the time came when the superintendent advised the construction of a plant, reporting at the same time the exact condition of the mine and ore reserves. All of this was most pleasing to the directors, and much deserved praise was given the superintendent. They then instructed him to submit to them estimates of the cost of such a plant as he considered advisable.

Machinery Houses

The superintendent immediately took up the matter with three well known machinery dealers, whose representatives visited the mine, and, in due course of time, each house submitted to him plans, specifications, and estimates of cost of the plant that the representative decided was best suited to the requirements. These plans and estimates were gone over carefully by the superintendent and some of the officials of the company. After many consultations and, needless to say, many visits from machinery house representatives, lunches at the club, and so on, a selection was made, and contracts signed. The elation due to the knowledge that they had a good, proved mine, well developed, with quantities of ore, together with their confidence in the superintendent, and the clear understanding the 'representative' seemed to have of their needs, shut from the view of the officials of the company the vision of anything but a successful plant. The machinery house furnished working drawings and an estimate of the cost of construction. Everything was most satisfactory to all concerned. The superintendent rushed the preliminary work, machinery was delivered, money paid, and construction soon under way. Exit joy, enter gloom.

In carrying on the construction, according to plans, it was found that the labor costs at each stage of the work were considerably in excess of the estimate given by the machinery house, due to conditions, such as the kind of labor available, which were not important factors in making the

estimate. The amount of material that had to be purchased during the construction was also surprising; not equipment, but all sorts of miscellaneous items, such as iron, lumber, nails, hose, wheelbarrows, track, and tools, besides material and equipment for an incline with which to handle the machinery to its proper site. All of these things made quite an additional amount of money necessary. As the plant neared completion, a metallurgist was employed to be its superintendent, and a crew was selected. All was ready and started, everything seemed to go smoothly, and all hands were jubilant. The added cost for labor and material during construction was forgotten. The next day the local newspaper announced that "The new up-to-date milling plant of the * * * Mining Company" was put into commission yesterday, and its operation was found to be perfect from the start. This plant has a capacity * * *," etc. I might here note that the metallurgist who had been employed as mill superintendent was not entirely satisfied with certain parts of the plant, but said nothing, as he needed the job and knew that it would work itself out.

Ore-Bin Difficulties

At the end of the second day the mine foreman reported that he could not put the amount of ore into the bin that he was instructed to deliver each day. The mill superintendent was questioned, and during the succeeding days he tried in every way possible to increase the capacity. Finally, at the end of two weeks, it was decided that the maximum had been reached, 30% less than what the plant was designed to do. The first blockade was at the regrinding mill, after the battery. The machinery house was appealed to and sent a man up to investigate, one who was able to sell machinery. First an attempt was made to make a second classification below the battery, so as to send a portion of the oversize to the tube-mill direct, with the idea of relieving the regrinding machine. This meant telegraphing for another cone to be sent by express. (Yes, it happened that there was sufficient height to get this in.)

Changes in the Mill

After the necessary tearing out of frames, and making of launder and plumbing connections, the cone was tried, but proved of but little help, and the amount of water added to the pulp in trying to separate a product for the tube-mill from the flow that should have gone to the regrinder was not small. It was clearly 'up to' the regrinder, and the man was forced to admit, not that the machine was not doing work up to its rated capacity, but that a much larger amount of pulp was going to it than was expected when the plant was designed. The ore was harder than had been realized, and too small an amount was crushed fine in the battery. Nothing for it but another regrinder. "Too bad, but one cannot always tell how ore is going to crush." The regrinder was ordered at once by wire from the East. Meanwhile, the plant was to be operated at the limited capacity. The crew must necessarily remain the same, hence the

cost of milling was increased 43%, amounting to \$1827 per month, or \$4575 for the 75 days before this new mill could be received and installed.

Fortunately, the superintendent inquired about the power necessary for this new mill and found that the motor which was driving the present regrinder, and some other equipment, was already fully loaded. Either a separate motor must be put in for the new mill, or the present one taken out and a larger one put in its place. The latter course was adopted, and by the time the new mill arrived, the new motor was installed on a new foundation with new transmission arrangements. The only place that this new regrinder could be placed was outside of the building, so it was necessary to remove a portion of the wall, make an excavation, build a lean-to addition to the building, put in foundation, and increase and alter the water service. On account of the distance that this placed the mill from the discharge of cones, the launders had to be reconstructed and the second cone thrown out.

Tank Changes

While running at the reduced capacity, waiting for the new regrinder, something went wrong with the vacuum pump, and it became necessary to stop the filter for a day to repair the pump. When the filter stopped, everything had to be shut down, all the way to the top of the mill, as no pulp-storage tanks had been provided. To provide against such delays in the future, two pulp-storage tanks, fitted with agitation appliances, were ordered at once and installed. In placing these tanks after the agitators, there was, of course, insufficient head room between the discharge of the agitator and the top of the settlers, hence it was necessary to provide a centrifugal pump to lift the stored pulp to the required height. There being no room in the building, or on the grades, for these large tanks, it was necessary to make a special excavation beside the building and build a retaining wall and foundation. This work was not foreseen at the time the material for the alterations to accommodate the new regrinder were ordered, consequently another less-than-carload order of cement and lumber was placed. A new motor for the agitators, alterations in plumbing, electric wiring for power and lighting, gangways, steps, and walks were all necessary.

Additional Equipment

When the new regrinder was installed, the capacity was run up to that originally proposed without difficulty. The classifier was the next point of trouble. It had not been handling the product quite as satisfactorily as desired, but now that the added load was put upon it, it became literally buried. It was not suited to the work and had not sufficient capacity. The question of adding another or throwing it out and putting in one of different design was decided in favor of the latter. This was ordered and installed. Meantime the plant was again being operated at limited capacity. The new installation involved, of course, another lot of alterations to power, lighting, water, and launder service. At this time the metallurgist in charge of the

mill determined that a good extraction could not be maintained if the time of agitation were shortened. With the capacity of the plant increased, this would be necessary, unless another agitator was added to those in use. (Note that the metallurgist had been employed at the time the plant was ready to run, but had been given no chance to determine such points in advance.) So in order to avoid further disappointment and delay, an additional agitator was wired for. This required an additional amount of air, which the compressor could not deliver. A new compressor was therefore ordered, with a new motor to drive it. All of this called for a deep excavation for the new agitator, additions to the building, a retaining wall and foundations for agitator, compressor, and motor, and also alterations in the air, water, and lighting service, and in gangways and walks. More less-than-carload freight shipments, and an additional 30 days' operation of the mill at limited capacity were necessary.

Precipitation Department

The precipitation department was nearly efficient. Clarifying tanks had been installed to save the cost of a clarifying press, and the results secured were, however, more or less unsatisfactory. This led to the purchase and installation of a press for the purpose. I understand that the metallurgical company that supplied this precipitating plant will not now guarantee satisfactory results unless a clarifying press is used. This is good, and will save added costs in this department. The amount of solution to be handled in the plant had been greatly underestimated, if estimated at all, and when the plant was brought up to its capacity this was keenly felt. In fact, it so handicapped the cyanide department that four additional tanks were installed to give sufficient storage capacity. This also necessitated another pump and a pipe-line to storage tanks at top of plant, and called for additional alterations in the power service and circulating system.

After all these alterations had been made, the increased tax upon the power service necessitated the purchase of a transformer. Other smaller items that had also to be supplied were: laboratory equipment, report and testing-room fittings and tools, and utensils and appliances for use of the crew. All of this was not done as easily and simply as it reads, as the reader will know from experience, but days were spent trying to make parts do their duty, scheming to overcome troubles, telegraphing for prices, and placing the stock. Also much loss of time, grief during the making of alterations, and losses of material which cannot be easily estimated. After four and a half months—which, by the way, was a short time, considering the various troubles, the plant was at last ready to handle its estimated capacity in an efficient manner. The additional cost over and above the original estimate was \$49,519. This total was made up of the following items:

Additional labor for construction made as per plans.	\$6,732
Additional cost of material as per plans.....	5,270
Additional freight and hauling of this material....	904
Cost of supplies used during construction.....	2,240
Equipment, material, and labor for necessary accessories	2,185

Equipment, material, and labor for surface incline..	1,373
Purchase and installation of cone classifier, with its attendant costs, and subsequent tearing out of same	180
Purchase and installation of new re-grinder, including excavations, building, foundations, and alterations	3,690
Purchase and installation of new motor, on account of additional power required for re-grinder, foundations, and alterations	620
Purchase and installation of pulp-storage tanks, including pump, motor, pipe and fittings, excavations, building, foundations, and alterations....	2,420
Purchase and installation of new classifier, including removal of old one, foundations, and alterations	980
Purchase and installation of new compressor and excavations, building, foundations, and alterations	1,010
Purchase and installation of new compressor and motor, including foundations and alterations...	1,440
Purchase and installation of clarifying press, including foundations and alterations.....	2,860
Purchase and installation of additional solution tanks, pump, and pipe-line, including excavations	680
Purchase and installation of new transformer.....	720
Purchase and installation of laboratory equipment, tools, and appliances	600
Freight and hauling on above new equipment and material	3,615
Added cost of operating expense for 4½ months, due to limited capacity.....	8,540
	<hr/> \$45,959

The difference between this amount and the actual added cost, as noted above, or \$3560, was made up of miscellaneous items of which no detailed account was kept, such as: telegraphing, express charges, traveling expenses, added office expenses, and experimenting. There should also be added the loss of the use of the money not produced, due to the 30% curtailment of the output for the four months and a half.

Total Cost

The total cost, then, was about 41% greater than the original estimate. This does not necessarily mean that the plant cost 41% more than it should have cost, but 41% more than the amount of money the company was advised it would cost and had arranged to have on hand to pay. It is quite annoying for a board of directors to be obliged to notify the stockholders every 30 days that more money is needed for construction work and at the end to realize that they have spent 41% more than they said they would. In this particular case there was no further embarrassment after the first call for additional money, as the profits from the operations at limited capacity amply covered the added cost. This good fortune does not, however, alter the seriousness of the underestimate, as many times this would not be the case. It may be added that where the excess cost is paid out of profits made during the operation of the inefficient plant, less attention is paid to the fact that excess cost was incurred, thus helping to keep it from public notice. But at the same time it indicates the underlying reason for the remark of a director, given above: "Add 75% to that amount and you will come close to actual cost, is my experience."

Cause of the Trouble

Having gone over the chief details of the history of this plant, the question at once presents itself, where did 'gloom' first enter? What was the cause of all this trouble? The answer is easy, and I only fear my inability to state it strongly enough to make the facts clearly understood and appreciated. The first error was made when the superintendent went to machinery dealers to buy a plant, instead of taking to them a complete set of specifications of what was wanted and asking them for bids. The point is this: When a buyer goes to a machinery house and tells them that he wants a first-class milling plant, of a certain daily capacity, giving them all the details possible of treatment required, the machinery dealer will prepare a set of plans and specifications, including as little equipment as will assemble to the appearance of a plant of the capacity desired. The buyer generally expects the dealer to put in every sort of thing possible in order to make the sale greater. As a matter of fact, they cut out everything they can possibly omit in order to quote as low a price as possible so as to get the order. You might buy the plant somewhere else, or not at all, if the price seems too high, but once you buy and install what they have specified, you will have to buy what the plant lacks later; their whole aim being to 'land' your order. They have no responsibility in the matter beyond supplying first-class specified equipment. They are not selling you a plant guaranteed to handle so many tons of your ore per day, making a certain percentage of recovery or profit, but they are simply selling a specified list of equipment. All efficiency and capacity statements are made by 'selling' engineers, or trade catalogues, and the firm's authorized signature will not be found signed to anything in the way of a guarantee, except the contract to sell certain specified machinery (of first-class workmanship and design) at a certain price and upon certain terms. Their principal concern is to leave out enough items to enable them to make their price lower than the other bidders, and at the same time specify enough to make the proposal look like complete equipment to the purchaser. There is a happy medium here which must be struck, and the expertness with which a machine salesman can do this measures his worth to his firm.

Position of Machinery Houses

It might be thought that the machinery business would be injured by such methods, but they all do it, and, no matter how conscientious a firm desires to be, they know that other firms will proceed in this way, and therefore they must, or not expect to secure the business. In the second place, it is easy enough to slide out of any responsibility not really assumed, cover their designs or intentions, and actually make the purchaser their friend by ready and willing assistance in securing the additional equipment needed. Persons who buy plants in this way rarely buy more than one, in any case. In the case under consideration, when it was found that the regrinding mill had not sufficient capacity, the claim that the ore did not crush as easily as

expected seemed plausible as well as probable.

Placing the Blame

Was it the fault of the superintendent? No, not exactly. When this man was employed, he was secured as the best man obtainable to develop the mine. He was not supposed to be a metallurgical engineer, and his knowledge along this line was superficial. He had not spent his life in designing and constructing milling plants, but in finding and developing ore. When it came time to build the plant, everyone was jubilant over success; this man had made good. The building of the mill did not appear to be anything to 'stump' him, especially when all the machinery houses were ready to help with advice and experience. The fault was with the directors of the company in not being as careful in beginning the milling business as they had been in starting the mining business. Had they had plans, specifications, and estimates carefully prepared by an experienced metallurgical engineer, no such annoyance would have occurred, no time would have been lost after installation, and the completed plant would have cost much less than the excess cost of the present one.

Conclusion

Some of my readers will doubtless think I am trying to score the machinery dealers, but this is not the case. Machinery dealers are the friends of mining operators and especially of metallurgical engineers; from them the engineer secures quantities of data and much assistance. Were they not friendly with each other, and did they not work together, supplying each other with information based on experience and practice, it would be indeed difficult to prepare a correct estimate of a piece of work. I have merely given the history of this particular mill as an example of one way in which excess cost occurs, and have stated the reasons given because they are true and, if personally understood, reflect in no way upon machinery dealers. I do not wish to be understood as blaming the machinery houses for methods they are plainly forced to adopt, but I certainly would be glad to see conditions changed so that such methods need not be pursued. Machinery houses much prefer to tender a bid on a full set of specifications rather than to deal with buyers as in the above case. When specifications are prepared, really competitive bids can be secured, the machinery houses are saved much unnecessary expense, and everybody is better pleased. A machinery dealer prefers to stick to his own business, that of manufacturing and selling machinery. Going to a machinery house to buy a milling plant, as in the case cited, is like going to a sawmill to buy a house. Submit specifications to the dealer and ask him his price in either case, thus doing away with the conditions which force him to do business in the manner described above. I suppose the time for this will never come, but if every machinery house would refuse to bid on a milling plant without having the buyer's own specifications to go by, this cause for excess cost would be eliminated.

The Symmes Agitator

By WHITMAN SYMMES

In sequence of the article by Jay C. Carpenter in the *Mining and Scientific Press* of May 3, it may be of further interest to metallurgists to have a description of my solution of the flat-bottom agitator problem. The results which Mr. Carpenter obtained are excellent, and quite remarkable. But in the operation of the Trent agitators at the West End mill, he was dealing with a much simpler ore than that being cyanided in the Mexican mill. This ore contains heavy lead, zinc, and iron sulphides, and treating without concentration, a much stronger agitation than that described by Mr. Carpenter is required, both for the solution of the silver and gold, and keeping the ore in suspension. For example, when Trent agitators were in the Mexican mill, it was impossible to start them, when they got stuck,

treated. An arrangement of Pachuea agitators, transferring to the Dorr thickeners, and receiving pulp from them, would have been inconvenient, because of the different elevations of the agitators and thickeners respectively. Therefore, it was desired to retain the flat-bottom vats, for metallurgical reasons as well as for economy in the alterations. At that time, the Dorr agitator was not upon the market. I knew of no agitator which would meet our requirements; and so it became necessary to devise one.

A Perfect Agitator

A perfect agitator should be capable of giving as strong or as weak agitation and aeration as any pulp requires; it should have no wearing parts in

VIEW SHOWING TOP OF VAT FITTED WITH SYMMES AGITATOR.

by the simple expedient of forcibly reversing the arms, as described by Mr. Carpenter. Indeed, the ore packed so solidly in the bottom of the vat, that the arms could not be made to clear themselves, even when the vat was emptied to within a few feet of the bottom, and men took hold of the arms and attempted to move them. Collars were always fixed to prevent the arms from rising, and consequently there was no trouble from that source such as Mr. Carpenter describes. At first there were steam coils in the vats, but scales of baked clay, from the crust formed on the pipes, would choke the nozzles, and consequently live steam had to be substituted for heating. I do not think that anyone could have given the Trent agitators a fairer trial for continuous agitation of the Mexican ore, than they received under the supervision of the mill superintendent, Charles R. Morris. Mr. Carpenter does not refer to any device, or to any method which was not tried there. The time lost in the mill, due to the Trent agitators, was in hours as follows: March, 1912, 28.6; April, 57.5; and May, 46.8.

In the Mexican mill it was necessary to change solution during the cyanide process, on account of the high tenor and baseness of the pulp being

the pulp itself; it should not be subject to interference or injury by settlement or packing of the pulp; and all parts should be readily accessible from the outside of the vat. To meet these conditions for a flat-bottom vat, I devised a machine consisting of a number of air-lifts, flexibly suspended from a horizontal revolving arm. In the Mexican mill these are supported from an arm on a standard, fixed immovably in the centre of the vat, and on account of the space available beneath each vat, the driving gear was placed there. The revolving arm could just as easily be suspended and driven from above, if the vats had been resting on the ground, and designed for operating by that method, if required. The agitator can be easily understood from the illustrations. The only parts beneath the pulp that require any attention are the air nozzles. These are protected with rubber sleeves, as in a Pachuea, to prevent a flow of pulp into the air-pipe, when the air-supply is interrupted. The air-lift tubes hang from the revolving arm by means of chains, and are so balanced as to remain vertical when the arm revolves, which in the Mexican mill is at the rate of 1.5 r.p.m. Air is supplied to each tube by a hose, connected with a pipe-union above the pulp. In the

event that the pulp becomes packed on the bottom of the vat, the air-lifts will drag, and cut their way down through it. A rod, rising from each tube, indicates whether the tube is in a vertical position, or is dragging. If power should be off for a long time, the air-lift tubes can be raised by means of the chains, and then, by being lowered a few links at a time, will cut their way down to their normal position near the bottom of the vat. For agitating a vat while it is being filled or discharged, when the air-lifts are unable to operate, a second air-pipe can be carried down alongside of each air-lift, and air

\$12, and discharging it at \$6 per ton. The new agitator took the pulp at \$12, and discharged it at \$4. The following figures show the improved extraction, other conditions being the same in both cases.

TRENT AGITATORS			Further extraction possible by agitation.
		Tailing.	
June	1912.....	\$1.58	\$0.23
July	1912.....	2.01	0.26
August	1912.....	1.64	0.20

SYMMES AGITATORS			Further extraction possible by agitation.
		Tailing.	
March	1913.....	\$1.67	\$0.03
April	1913.....	1.01	0.02
May	1913.....	1.30	0.04

The undissolved metal of value is practically all silver.

Details of the Agitator

The agitator tanks are 24 ft. diam. by 14 ft. deep. The power consumed by each of the three Trent agitators, for the pumps alone, averaged 6.31 hp. The power consumed in turning the revolving arms of each of the new agitators is less than 0.5 hp., and the compressed air used is equivalent to about 4.5 hp. at the motor which drives the compressor. The latter is a Sullivan, 18 in. diam. by 12-in. strokes, built without a water-jacket, and supplying air at 12 lb. pressure. It is operated at a speed of 93 r.p.m., and supplies all the compressed air used in the mill, for operating three air-lifts, a 16-ft. Oliver filter, the three new agitators, and a No. 525 Steel-Harvey crucible furnace. The compressed air consumed by the agitators, measured by an Excelsior air meter, is

may thus be blown into the partly filled vat, but in the Mexican mill the continuous system of agitation is in use, and these extra pipes are not needed. The amount of compressed air used by each air-lift is regulated by means of a needle-valve above the connection, and for this purpose the attendant can walk along the trussed beam while it is revolving. The suspended air-lifts can be easily lifted out of the vat for inspection, by merely disconnecting the air hose at the union, and then lifting the chains off the hooks. There are no flange connections below the level of the pulp, to be cut by action of the moving pulp, and thus made to leak, as in the Trent and some other types of agitators. There are no valves necessary to hold the pulp in the vat, while making repairs to pumps or pipe-lines, and which valves, having been cut by the moving pulp, are generally found to leak badly. There are no pumps to pack and to repair.

The Agitator at the Mexican Mill

The first agitator of the above description started operation in the Mexican mill on August 30, and the second and third were started on November 20, 1912. They are still in operation, and the crushing and grinding department of the mill has never lost any time on their account. They have never been shut down except when the power was off, or when the air-lifts have been lifted out to inspect the condition of the rubber sleeves, which is done about once a month. They have never required any repairs whatsoever, excepting new rubber sleeves. When the first agitator was substituted for the Trent, its superior agitating power was at once apparent. No. 1 Trent had been filled with pulp sampling about

SECTIONAL ELEVATION OF SYMMES AGITATOR.

as follows: pulp, 1 ore to 2 solution, with air 8, 12, and 15 lb. pressure, consumed 29, 80, and 94 cu. ft. respectively, while with 1 ore to 2½ solution, with same air pressure, consumed 30, 74, and 89 cu. ft. respectively. The agitators are ordinarily working with air at 12 lb. pressure or less, and their average consumption is 60 to 70 cu. ft. of free air per minute. The amount of air required depends upon the violence of the agitation which the pulp demands, in order to obtain a complete extraction, and does not depend upon the agitator itself. In one test the

pulp was thinned to 1 ore to 3½ solution, and agitated with only 17 cu. ft. of free air per minute at 8 lb. pressure, without there being any settlement of the pulp to the bottom of the vat. No difference was noticed in the operation of the agitator when the melting furnace was drawing upon the air supply, and probably they could be operated with less air than at present. The agitators require less attention than any other machinery in the Mexican mill, and except for a slight alteration of the piping, which has since been devised, they appear to be as near perfect as it is worth while trying to get. The power has been off for 5 hr. 40 min., and they started without any trouble. It has never as yet been necessary to raise or lower the air-lifts in order to have them cut their way back to the bottom of the vat, and as the indicating rods have not been of any particular use, it is doubtful if they are really necessary. After stoppage, the air-lifts seem to start the agitation by dragging and by cutting their way by means of the induced flow. They appear to be better than the Dorr agitator, in that they have no rakes to be buried in the pulp. I infer this from the similarity of the Dorr agitator to the Dorr thickener, and know that, in the latter, the spider can be broken by settlement of the pulp, owing to lack of attention. Furthermore, our agitators make use of the full capacity of the vat. I believe that they are in every way as good as Pachucas, with the additional advantages of a less first cost, of an absolute freedom from interruptions of the agitation, and the possibility of a cheaper and more convenient arrangement in connection with the now almost universally used Dorr thickeners.

Section 10 of the Mines Act of 1907, of Victoria, Australia, provides that any water or sludge produced from or consequent to any mining operations, and discharged into any watercourse, lake, or reservoir, shall be deemed to pollute or injure the same if such water or sludge, at the point where it leaves any claim or any land comprised in a lease, or any land used in connection with any such mining operations, by or in any respect under the control of the person carrying on the same—(a) contains any poisonous matter in the total proportion of more than 50 gr. to 1 gal., or any noxious matter in such quantity as to be injurious or detrimental to the public health; or, (b) holds in suspension or solution any earth or mineral, or any earthy or mineral substance in the total proportion of more than 800 gr. to 1 gal. A watercourse includes river, stream, watercourse, waterway, creek, or gulch, and in each case whether water flows therein perennially or intermittently.

The Buffalo Star dredge, Bright district, Victoria, Australia, handled 377,519 cu. yd. of gravel in 1912 yielding about \$42,000 in gold. This was from a depth of 33½ ft. The company has re-soiled about 2330 sq. yd., about ½ acre of dredged ground, by carting soil from ahead of the dredge and spreading it from 15 to 18 in. deep on the tailing from the dredge. In December last the oat crop was 4 ft. high, cutting equal to two tons of hay per acre, or 60 bushels if thrashed.

Diamonds and Other Gems Mined in the United States

Gems and precious stones were produced in the United States in 1912 to the value of \$319,722, according to Douglas B. Sterrett, of the United States Geological Survey. The kinds of precious stones found in the United States are many, ranging from diamonds of fine quality to low-grade stones such as agates, but, as is seen from the total value of the output, there are no really large operations.

The principal gem mineral mined in the United States during 1912 was Montana sapphire, of which there was a large output for use both as gems and in mechanical applications. The greater part of the gem sapphires came from the mines in Fergus county, where they occur in a rock matrix. The majority of these stones have the true sapphire-blue color. The bulk of the sapphire for mechanical use came from the placer deposits in Granite and Deer Lodge counties and consists of varicolored stones.

The development of the opal deposits of Humboldt county, Nevada, was attended with much success, and a quantity of magnificent gem material was obtained. The opal is of an unusual type, consisting of dark translucent mineral with a variety of rich colors. The deposits promise to supply a gem equal if not superior in beauty to the opal from Australia.

Prospecting and mining at the emerald mine in North Carolina were attended with only partial success. Two pockets or deposits of emerald were removed during the year; other developments consisted mainly of exploratory work, which has continued into 1913.

The tourmaline output of southern California was small, but some magnificent specimen crystals were obtained. Especially fine gem crystals of kunzite were found and brought good prices. The production of turquoise was very small compared with some previous years. Beautiful amethyst was found in Warren county, North Carolina, and some fine gems have been cut from sample crystals. A few fine specimens of golden beryl were obtained from prospects in Alexander county, North Carolina. Beautiful gems were cut from some of these. The production of agate and associated varieties of chalcedony was again large in several Western states.

No great advances are reported in diamond mining in Arkansas during 1912.

Several dozen diamonds were found and several diamond-washing plants were constructed for operation in 1913.

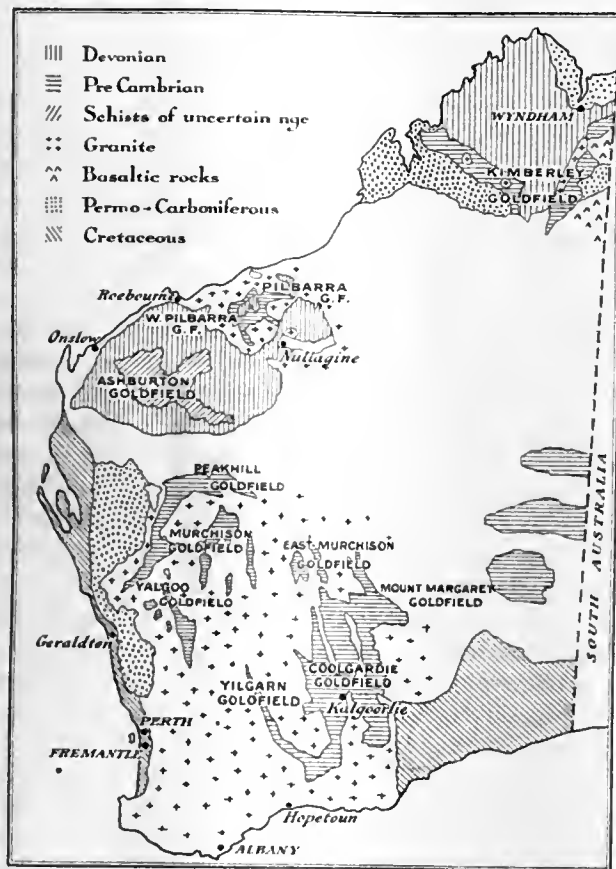

It has been practically impossible to determine the quantity and value of the diamonds found in the Arkansas field since the first discovery in August 1906. Most of the stones are still held by the mining companies and few have been sold. It is estimated from the figures furnished the Survey and from reports in the press and those furnished by private persons that about 1400 diamonds, weighing nearly 550 carats, have been found from August 1906 through December 1912. The total estimated value placed on this output in these reports amounts to \$12,108.

Geology of the Kalgoorlie Goldfield—II

By MALCOLM MACLAREN and J. ALLEN THOMSON

General Geology and Geological History

The area here briefly described lies between the 121st and 122nd meridians of east longitude, and between 30° 30' and 31° 05' 18" south latitude, being approximately 40 by 59 miles and containing 2375 square miles. A general grouping of the rocks and deposits of the region may be made, in order of increasing age, as follows:

GEOLOGICAL MAP OF WESTERN AUSTRALIA.

(a) Recent and Pleistocene:

Drift sand, salt and gypsum (*kopai*) beds, calcareous cements, laterite (ironstone), kaolin clay ('pug'), magnesite deposits, alluvial 'wash', and valley and lake deposits in general.

(b) Pre-Cambrian:

1. Younger granite and quartz-porphyry.
2. (a) Younger Greenstones: serpentine, talc-schist, gabbroid rocks, coarse amphibolite, epidiorite, quartz-dolerite greenstones.
- (b) Porphyrite and felspar-porphyry.
3. Sedimentary Beds: shale, chert, quartzite, and conglomerate.
4. Older Greenstones: fine-grained amphibolite, calc-schists.
5. Gneissic granite (not as yet known in the region).

From the foregoing it will be apparent that there are essentially two rock groups: (a) a pre-Cambrian rock complex; (b) the denudation under desert con-

ditions of that rock complex. The former is of chief concern.

A small-scale map of Western Australia would show the rocks of the area in question as a comparatively narrow band of greenstones, striking N.N.W.-S.S.E. in a wide area of granite. The band is widest from Coolgardie through Kalgoorlie to Kurnalpi, a distance of 75 miles; to the north and south there is an appreciable diminution in width, the greenstones indeed bifurcating northward (north of Broad Arrow) into two big narrow parallel belts. These changes are not, however, appreciable within the area here discussed, which indeed is almost entirely occupied by the greenstone complex, and shows only small areas of the enclosing granite near Coolgardie on the west, near Black Flag on the north, and at Juglah on the east. East and west of the area the granite outcrops for many miles.

Dealing then with the greenstone complex, the known rocks may be separated into three main groups: Older Greenstones; Sedimentary Beds; and Younger Greenstones, with which are associated porphyrite and porphyry dikes. The internal relations of these are naturally exceedingly obscure on the amount of mapping done, and it is certain that more detailed work would effect considerable local modifications.

Older Greenstones

The Older Greenstones together with the ancient sedimentary beds occupy the major portion of the area. The former are mainly fine-grained amphibolites, with allied or more probably derivative rocks generically termed calc-schists. Both names have only a general significance and give no clue to the original character of the rocks; an amphibolite is merely a hornblende-bearing rock and a calc-schist an indefinite rock characterized by abundance of secondary carbonates, as dolomite and siderite. They form in the field low, long, and broken ridges, which yield low swelling knolls, a physiological form fairly characteristic of these rocks. Their weathering yields a talus of small rectangular fragments, which break with an approach to conchoidal fracture. Future more detailed mapping should reduce the area allotted to the Older Greenstones, since they have been utilized to embrace all doubtful or insufficiently examined rocks; they will in their reduction yield nothing to the sedimentary beds, but a great deal to the Younger Greenstones. Little may be said concerning the original nature of the rocks grouped as Older Greenstones; they may have been tuffs and ashes, or they may have been lava flows. It seems reasonable to regard them as representing alternations of lavas and ashes, the former furnishing the fine-grained amphibolites, the latter the calc-schists. The Older Greenstones are perhaps most typically developed in the great bands east of Kalgoorlie, for the broad western band at Coolgardie has been so altered by

the intrusion of the younger granite that it has lost many of the characters of the original zoisite-amphibolite (a hornblende rock characterized by the presence of the mineral zoisite).

Sedimentary Beds

In the absence of direct evidence of the nature of the Older Greenstones it is impossible in a time classification to separate from them the ancient indubitably sedimentary rocks of the area. The latter present a normal cycle of sedimentation ranging from coarse conglomerates to fine muds. They are best developed in the neighborhood of and to the south of Kurrawang; they will therefore henceforth be collectively termed the Kurrawang series. Between Coolgardie and Kalgoorlie the sedimentary beds are eleven miles broad across their strike; they run north-northwest across the low ground of the Kurrawang lakes, and pass some distance west of Black Flag. To the south they are lost in low lake country, and do not appear to pass beyond the great Mt. Monger thrust plane.

The series is well exposed in a long line of so-called 'breakaways' that lie on the edge of the 'lake' bed about two miles south of the main Kalgoorlie-Coolgardie road between Binduli and Kurrawang. The sediments remain above the lowest surface levels only with difficulty and only when they have been strengthened by ribs of conglomerate or by dikes of intrusive acid rock; the finer-grained rocks are therefore rarely seen and are ordinarily covered by lake deposits and by wind-blown sand. The conglomerates or 'boulder beds'—the latter is the better appellation—are only sporadically distributed through the sediments, and their appearance is reminiscent of the scattered beds of conglomerate of a great river valley, as that of the Brahmaputra, the individual beds being thin and soon running out to a feather edge. Their greatest development is in the high ground immediately southeast of Kurrawang, where they occupy the ridges and run as far south as Red lake. On the same strike they reappear to the north of the broad low Kurrawang valley in the ridges immediately west of the Black Flag lake. They are here and near Kurrawang composed chiefly of pebbles of quartz, quartzite(?), jasperoid rocks (often banded), and albite-porphry, all being sparsely distributed in a schistose felspathic matrix. The individual pebbles are often so sheared that they show a succession of minute step-faults; where the pressure has been less severe they are generally deformed. They thus conform to the general type of Archean conglomerates in their scanty distribution through a schistose felspathic and often chloritic matrix. They have, therefore, been claimed by glacialists as products of ice action; but there is nothing in their distribution or in their internal characters that cannot be better explained by invoking the assistance of large tropical rivers, such as the Irawadi and the Brahmaputra of the present day.

Minor Areas

The grits associated with the conglomerates are ordinarily felspathic and come therefore under the old definition of greywacke. Occasional flakes of

biotite with derivative chlorite are also found. The general arrangement of the quartz and felspar is indicative of strong shearing.

In addition to the broad Kurrawang area of sediments, three others of minor importance and much more ill-defined are known. Their position may often be traced only by the valleys that result from the lack of resistance offered by these rocks to the agents of denudation. They are all east of Kalgoorlie, the first lying in the long valley that runs down to Hannan's lake along the eastern slope of the Kalgoorlie ridge. This valley was largely used as a source of salt-water supply before fresh water was brought to the goldfield from the coast, and several water-shafts are scattered along its length. Their dumps furnish no information, and the only good exposure is in the Phoenix quarry, north of Hannan's brewery. Even here the rocks have been so crushed and altered that a sedimentary origin cannot be postulated for them with certainty, and the valley has, as a matter of fact, been mapped as a sedimentary area largely by comparison of its weathering products with those of the undoubted sediments of the Kurrawang area.

Much the same would have had to be said for the second band of sediments near Kurramia, were it not for the fortunate discovery of a small band of scattered boulders and pebbles in a cutting on the wood line tramway about one and a half miles east of Kurramia station. In this area also the width of the sediments, about three miles, is indicated by the width of the flat valley bottom. The eastern boundary is extremely indistinct since, and especially along the Kalgoorlie-Kanowna road, the sedimentary beds appear to join the Kanowna sheared-porphry area, the surface of which also tends to sink to valley bottoms.

Secondary Sediments

The third area of sediments lies to the northeast. Its western boundary appears to lie near Penny's Find, about 17½ miles from Kurnalpi. Two miles farther east the road passes through a break in a low ridge, which, to the south of the road, shows beds of conglomerate rising to the top of the ridge. The pebbles of this conglomerate are chiefly basic amphibolite with banded jasperoid quartz, and are thus sharply differentiated from the conglomerate bands of the Kurrawang and Kurramia areas. The presence of basic amphibolite pebbles naturally raises the question of the age of the sedimentary beds, and since the amphibolite resembles the rock of the Older Greenstone rather than that of the Younger Greenstone, it is assumed that the sediments are younger than the former, which is undoubtedly the case.

Younger Greenstones

Under the general title of Younger Greenstones are included several rock species, which are, however, regarded as representing successive segregations from a single common magma. Their wide divergences as well as their close relationship is perhaps best indicated by the following table. For purposes of description, the intrusive dikes of porphyrite and albite porphyry, though they do not

strictly come under the heading of 'greenstones,' are included here: Kurrawang valley to reappear much more clearly defined, both in position and in character, west of

Probable original rock.		Now represented in the field by:
Ultra-basic	A. Peridotite	Serpentine, talc-schist, coarse carbonate rock.
"	B. Pyroxenite	Coarse hornblende rock.
Basic	C. Hornblende-dolerite	Lustre-mottled amphibolite.
"	D. Gabbro or dolerite	Epidiorite.
Sub-basic	E. Quartz-gabbro or quartz-dolerite	1. Epidiorite with micropegmatite.
		2. Chloritic rock with micropegmatite (quartz-dolerite greenstone).
		3. Bleached and carbonated rock with micropegmatite ('granite' of the miners at Kalgoorlie).
Intermediate	F. Porphyrite	Porphyrite.
Acid	G. Albite-porphyry	Albite-porphyry.

The younger acid members are found intrusive into the intermediate and basic members of the complex. By far the most important member of the series, from an economic point of view, is the quartz-dolerite greenstone, so well developed in the Kalgoorlie mines, and, in its typically productive form, restricted, so far as examination has gone, to that area.

Ultra-Basic Rocks

The ultra-basic rocks have their greatest development in the neighborhood of Bulong. The serpentine arising from the alteration of the original rock, a peridotite, is often indicated, in the absence of rock exposures, by the magnesite boulders and fragments strewn over the surface of the soil. The long dike of ultra-basic rock running along the Boorara ridge and passing west of the Halfway hotel on the Kalgoorlie-Bulong road was thus first indicated. Nearer Kalgoorlie ultra-basic rocks occur in the north end of the Kalgoorlie belt and also in some profusion east and northeast of Mt. Hunt (or Mt. Robinson, as it is locally termed) four miles south of Boulder. Another small area is found west of the true Mt. Robinson, which lies eight miles east-northeast from Coolgardie. These areas were originally mainly peridotites, but with them occasional patches of pyroxenite appear to be associated.

The next group of rocks in this series includes quartz gabbro and quartz dolerite (diabase) now represented in the field by amphibolitic, epidiorite, and quartz-dolerite greenstone, the minor variations in rock features represented by the three latter types arising from slight original differences (generally in basicity) set up by segregation within a magma and also from differences in degree of later alteration. These rocks constitute, with the ultra-basic rocks, the great mass of the Younger Greenstones. Their greatest development is probably at Kalgoorlie, where the intrusive dike (the 'Kalgoorlie Dike') is $1\frac{1}{2}$ miles wide. They occur normally as dikes in the Older Greenstones or in the sedimentary beds, and from this feature, which is best shown by the dike near Mungari and by its northward continuation in the Kurrawang valley, the relative ages of the two great series of greenstones is established.

Gabbros

The obviously gabbro members of the Younger Greenstones show remarkable persistence in direction. Two main bands have been made out, the first lying along the Abattoirs ridge, west of Kalgoorlie, and the second passing through Mt. Monger. The first passes away to the south along the ridge south-west of Mt. Hunt; northward it dies away in the

the Lady Bountiful. Farther north and a little distance southwest of the Slippery Gimlet mine, the band shows a much fresher rock. Here the pyroxenes are quite unaltered, and the structure is that of a normal gabbro. The second gabbro band is shown by the dark green band passing through Duplex and Simplex hills to near Mt. Monger township and so to Badalbi hill. This belt may be traced on the surface by its peculiarly dense vegetation, carrying a low branching shrub that reaches a height of three to four feet and is not so seen elsewhere.

The original dolerites (diabases) are not so strongly marked in the field as the gabbros. They form strong ridges, which are, however, not persistent. They now occur as epidiorite, or, if very much altered, as amphibolite. It may well be that in this group rocks of two ages are included, for certain dikes; for example, one crossing the road near the 39-mile peg on the Kalgoorlie-Bulong road, have a north-south strike, while the regular strike of the majority of the bands is north-northwest to north-west.

Some of these do not differ greatly from the country of the Kalgoorlie lodes, and probably would have resembled that exactly had they been wider and had thus greater opportunities for a more complete segregation of acid and basic components during cooling. The variations from the normal type on consolidation and the later changes induced by pressure and the passage of underground solutions will be fully detailed in later pages.

Porphyrite

The next member of the segregation series to be considered is porphyrite. This rock shows considerable variation in appearance when collected over a large area, ranging from dark gray to bluish rocks like diorite to light porphyrite rocks distinguishable with difficulty from felspar porphyry. They are all, however, characterized by the presence of notably large well shaped crystals of felspar. The felspar porphyries also show these large crystals, but do not contain the hornblende or the biotite (black mica) that are found in the porphyrites. Some varieties of porphyrite show little groundmass and few large felspar crystals; these are diorite-porphyrites. Others show a considerable amount of groundmass with large crystals of felspar, hornblende, and biotite; these are hornblende-porphyrites or mica-porphyrites, as the hornblende show remarkable persistence as bands. The bands immediately west of Kalgoorlie may be traced southward by Feysville, and may be correlated with an obscure highly

sheared rock lying on the plain east of Wolluba. This band reappears beyond the Kurrawang valley on the ridge east of Mt. Black Flag, and farther north broadens considerably. At the Slippery Gimlet mine the rich lode now being worked lies in this rock, which is more easily recognized in the hand specimen as a porphyrite than under the microscope where the coarse structure is not apparent and the only name suggested for the rock is amphibolite, a useful general term denoting merely a hornblende rock and giving no clue to the nature of the original rock.

Other porphyrite areas are the neighborhood of the Majestic leases on the Randalls road; the country of the Queen Margaret lode at Kanowna; the Halfway Hill on the Gindalbie road; and near the 12-mile peg on the Coolgardie-Kunanalling road. The porphyrites weather badly and their limits are generally difficult, and often impossible, to trace. They, moreover, weather as to the west of Mt. Hunt, to a product resembling a decomposed highly felspathic grit, and in this state may readily indeed be confounded with the true sediments of the Kurrawang series. It is also suspected that sheared porphyry areas furnish much the same weathered product and in these cases there is considerable doubt as to the original character of the rock, whether sheared porphyry, sheared porphyrite, or felspathic grit.

Albite-Porphyry

Probably closely connected in origin with the porphyrites is the albite-porphyry (also termed soda-porphyry and felspar-porphyry), which occurs in narrow dikes, striking as a rule with the country in a general north-northwest direction. It is best known at Kalgoorlie and Kanowna, few exposures having been found outside those centres. Their general features will be described in detail when dealing with the Kalgoorlie field. In the vicinity of Kanowna albite-porphyry of two ages is known. A broad band of this rock has been crushed, brecciated, and occasionally mashed; its occasionally rounded fragments have been regarded by several observers as pebbles and boulders in a conglomerate, while the southwestern mashed portion (above mentioned) has been claimed as a felspathic grit giving confirmatory evidence of sedimentary origin. The fragments are cemented by quartz. Throughout the whole band, however, there are only two kinds of fragments, albite porphyry and a sheared rock found near the northern boundary of the area and representing the basic greenstone which is developed on that side. Finally there are no quartz pebbles in the band. Considerable light is thrown on the origin of this crush-breccia by the Binduli quartz-porphyry dike, which on being followed southward into the lake country, passes gradually from solid quartz-porphyry into a breccia in every respect similar to that at Kanowna, all stages of the passage being obtainable. The Kanowna crush-breccia is penetrated by a broad albite porphyry dike, along the walls of which the main White Feather lodes have been developed. In this rock also the rich flat quartz-veins of the Red Hill at Kanowna have been formed.

Granite and Quartz-Porphyry

It has already been shown that the Kalgoorlie area as described above forms a portion of a band of greenstones enclosed within granite. The greatest area of granite within the area is found in the southwest near Coolgardie, where the normally even N.N.W.-S.S.E. boundary of the granite and greenstone is broken by long western tongues of greenstone brought into their present position by faulting along thrust planes. Tongues of granite are also intrusive into the mass from the south crossing the Red Hill road 10 and 15 miles southeast of Coolgardie. The granite is the normal biotite granite. Its contact with the greenstone certainly does not dip flatly to the west, for a diamond-drill bore in the granite (in search of artesian water!), sunk from a point a little west of the boundary, reached a vertical depth of 2300 ft. without meeting greenstone. Near Black Flag there appears the southern termination of a tongue of granite that splits the greenstone band in two, the western portion of the greenstone running out to a point in the wide granite area near Davyhurst. A small granite area is present at Juglah. The granite rarely appears at the surface, but its presence may nearly always be assumed with certainty from the white sand that its disintegration affords. Where it does appear above the surface it furnishes the 'gramma' holes of the natives; for regions that have not been visited in Western Australia the existence of large well defined gramma holes is assumed to be indicative of a granitic area.

The quartz-porphyry dikes that occur within the greenstones are to be considered tongues or apophyses from granite masses either now exposed to the east or west or concealed at great depths beneath the greenstones. They are therefore most frequently found toward the margins of the greenstone bands; none are known in the immediate neighborhood of the Kalgoorlie mines. They are intrusive both through the Older Greenstones (at Coolgardie) and through the sedimentary beds (at Binduli). The largest area of quartz-porphyry known within the greenstones is perhaps that lying five miles northeast of Kanowna where the quartz-porphyry forms the bold hills overlooking the flats that were the scene of the 'Sacred Nugget' rush of bygone days. Another large area is in the neighborhood of Hunt's old dam at Wongi, in the south of the area. These dikes may often be traced, like the granites, by the clean white sand they yield at the surface.

Geological History

The clearest view of the internal relations of the goldfield rocks may perhaps be obtained by recapitulating the geological history of the region, and, with the foregoing facts at command, it becomes possible to outline at least its salient features. Since all the important events in that history took place at a time inconceivably distant—perhaps 15, perhaps 25 millions of years ago—and since it was a period of great stress, during which some of the components of the rock complex lost or masked their identity, the history may err somewhat in the sequence of minor events; that it is possible to re-

construct any portion of its history is due to the fact that to its troubled youth there succeeded a long life of strongly contrasting quietude during which the region has gently oscillated—moving perhaps an inch in a century—in faint response to world stressing forces that have beaten with little effect against the great rock buttress on which the goldfields of Western Australia lie. One other such region there is in the world, so similar in its rock composition and in its life history as to suggest that it forms the northern portion of a province, of which the middle portion has disappeared beneath the waters of the Indian Ocean, leaving the southern Western Australian section still uncovered. It is the Deccan region of southern India, and its previous examination has greatly assisted me toward the elucidation of the general problems afforded by the older rocks of Western Australia.

There is, in the small area studied, no exposure of the ancient gneissic floor on which the oldest rocks were presumably deposited. These gneisses do occur far to the east of Kalgoorlie, and they are also, it is believed, brought up by block faulting in the neighborhood of Albany; they may therefore be below the present surface, or, on the other hand, they may, and there is probability in the assumption, have been absorbed by later granitic magma as it 'stoped' its way toward the surface. That there were granitoid rocks is apparent from the pebbles in the conglomerate already described.

Sub-Kalgoorlie Formation

A broad granite area may therefore be imagined as the foundation on which the Kalgoorlie rock complex has been built up. Of its age, nothing can be said. It was before time, even as the word is understood in its geological sense, commenced to exist. It may indeed have been a portion of the fundamental gneiss of the older geologists, conceived by them to be the original product of surface solidification on the cooling of the earth. Its origin is immaterial, and further speculation concerning it is profitless. For long ages it lay bare in a world devoid of life, animal or vegetable, but at length there came an epoch that saw it shaken and riven by the forces of compression and tension that have molded the earth's surface; and up and through the fissures thus made, urged by the same lateral pressure or by the same release from overlying pressure that had induced the fissures, there welled a great lava magma that, emerging through volcanic foci, covered the surface far and wide with lava flows, and, when much steam was present in the magma, with volcanic ashes. The first lavas were akin perhaps to andesite and basalt, and were succeeded in the natural order of the segregation of magmas, operating then, as now, by more acid lavas as trachyte and rhyolite. These rocks form the Older Greenstones. It is probable that the expiring effort of that cycle of igneous activity sent acid dikes (aplite, pegmatite, quartz, and felspar-porphyry) ramifying through the lavas and ashes; so much is indicated by the conglomerates of the sedimentary beds. The crushed and brecciated felspar-porphyry area of Kanowna may well belong to this period. After the solidification of these rocks earth-

stresses engendered fault fissures and thrust planes, the filling of which with silica and iron oxides gave rise, but only near the surface, to bands of jasperoid rocks that rose to form the ridges of the country.

Erosion Agencies

On these rocks, then, the rains and winds and rivers of that far-off time acted as they would act today, decomposing and disintegrating the surface and transporting the resulting debris to lower levels. Only in rare cases were the lavas sufficiently resistant to form and to remain pebbles; ordinarily they were broken to sand and triturated to mud. The boulders of the coarser sediments therefore represent merely the harder ribs of the land; quartz-pebbles from quartz 'blows' and veins, banded jasperoid pebbles from the jasper ridges, aplite, pegmatite, quartz-porphyry, and felspar-porphyry from the dikes that seamed the country, and finally a few granitic pebbles from the presumably more distant granite mountains. These with much fine sand constituted the burden the great rivers carried toward the sea. The general facies of the sediments thus laid down indicates that the sea had not been reached within the Kalgoorlie area, but rather that the region lay in the track of a great river, as the Ganges or Brahmaputra, and that it was, like them, subject to periodic floods. The sporadic distribution of the conglomerate beds, together with the comparatively wide separation of individual pebbles, point to a river changing its channel from season to season and so moving laterally across its plain, and to a situation near the embouchure of that river from a high mountain range.

This concluded what may conveniently be termed the first stage in the geological history of the region; a great river plain had been formed, and from it there rose foothills of igneous rocks succeeded by distant mountain ranges and peaks of granite, from the deep valleys of which a many-branched river ran to the alluvial plain. No auriferous lodes or veins had then been formed in the rocks, and their debris therefore carries no ancient 'leads' or 'gutters'; whatever gold these Older Greenstones and sedimentary beds may carry, and it is little, is due to impregnation during a long subsequent epoch.

Effect of Compression

The region was now subjected to intense horizontal compression acting from E.N.E. to W.S.W. The horizontally bedded sediments and the then little-altered volcanic rocks were involved in the compression and were buckled into long low waves which became narrower from crest to crest until at length they were crowded on each other in intensely sharp folds, carrying far below in the bottom of the folds, the rocks that had originally been on the surface. The rocks have been crowded together so closely that it is now impossible to say whether the five bands of Older Greenstone—namely, at Coolgardie, Kalgoorlie, Boorara, Balagundi, and the Bullock Holes—are five separate beds of lavas and ashes, or are merely preserved portions of one and the same series; the same may be said with regard to the four bands of sedimentary beds.

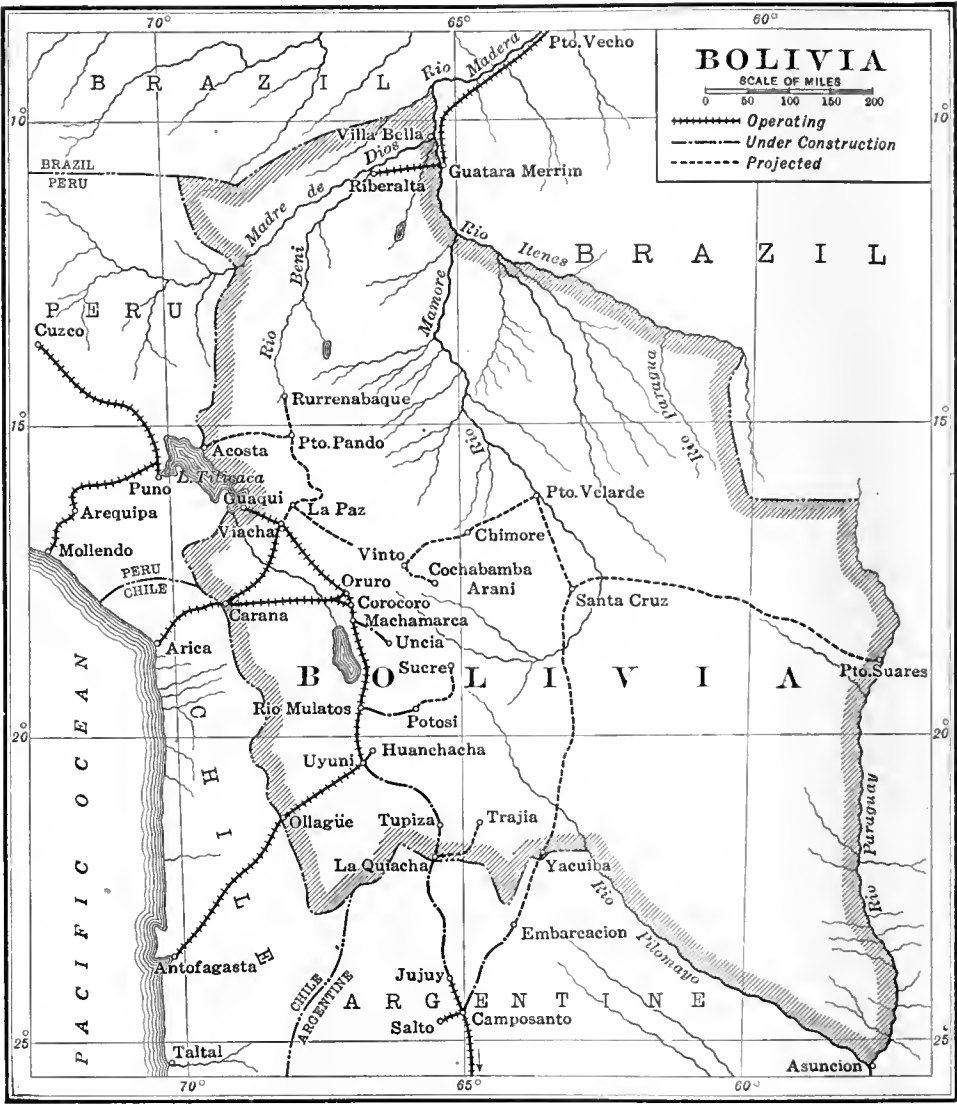

Railroads and Transportation Problems in Bolivia

By G. W. WEPFER

This article is written primarily in the interest of mining engineers and prospective investors in Bolivian mines, for the purpose of shedding some light on Bolivian conditions and the future possibilities of the mining industry in that country. Three successive presidents of Bolivia have been working for the settlement and peaceful development of the coun-

Silver v. Tin

The city of Potosi was founded in 1545 and by 1595, before the settlement at Boston, it had a population of 160,000 inhabitants. The ore in this locality is as rich as when mined by the Spaniards in the colonial days, and there is more of it in place today

MAP SHOWING OPERATING AND PROJECTED RAILWAYS OF BOLIVIA.

try. President Pando arranged the frontier dispute with Brazil, President Cornel Montes made peace with Chile, and President Villazon is at present following the same policy. Within the country there is a difference in elevation between the *pampas* of the east and the snow-covered peaks of the Cordilleras of more than 20,000 ft. The food products of the temperate and the tropical zones supply a great part of the population of the Andean plateau and the miners in the Cordilleras. Further railroad and river navigation facilities are required to carry the products for export to the ports of Antofagasta, Arica, and Mollendo on the Pacific and to Para, Buenos Aires, and Montevideo on the Atlantic, and will undoubtedly soon be furnished.

than mined by the Spaniards. The silver ore is not mined as much as the tin ore, which the Spaniards had no use for, and had left in the mines. As tin at the present time pays better than silver, it is given the preference. In most parts of Bolivia the wages of the ordinary miner is 60c. per day, from which the miner buys his own food. In the barren parts of the country and where food has to be brought a long distance, as at Potosi, wages are much higher. The silver and tin concentrates from Potosi are carried by llamas to the Pacific coast in the same manner as they have been for the past 368 years. The llamas require fifteen days to make the trip from Potosi to Uyuni. The new railroad from Potosi to the station at Rio Mulatos on the Oruro-Antofagasta line, which

will be opened this year, will require not more than 12 or 15 hours for this trip. When this line is opened, provisions can be delivered cheaply at Petosi which will result in a reduction in the high wages and also the freight charges to the coast ports.

Drilling is done entirely by hand at the present, and if air, electric, or oil drills were introduced a great saving in the cost of mining would be effected. Distillate and crude oil can be obtained from the Peruvian side of Lake Titicaca. These improvements will result in a more profitable working of ores for gold, silver, tin, copper, antimony, bismuth, tungsten, wolfram, and other minerals. The tax on mineral lands is only 60c. per pertenencia (2.47 acres) each 6 months. The export tax on metals is 1c. per ounce of silver and 20c. per ounce of gold.

Andean Plateau

In sheltered parts of the Andean plateau are fertile valleys which abound in wheat, corn, fruit orchards, and flowers. Cochabamba, a city of 25,000, and Lucre, with 20,000 inhabitants, have beautiful parks and pleasant surroundings. The families of many of the mining engineers reside here. Some live on the farms, as the natives are kindly disposed toward foreigners. The hot springs at Coleha are sought by many as a cure for rheumatism. Savage Indians are still in the country, but it is hoped that by their association with semi-civilized Indians they will be gradually raised to a state of usefulness.

Bolivia has an area of 59,721 square miles and a population of 2,500,000, including 240,000 savage Indians. The greatest part of the population are living on the Andean plateau and the eastern Cordilleras.

The first railroad in Bolivia, which was built between Antofagasta and Oruro by the Huanchaca Mining Co., was a 30-in. gage line and was splendidly equipped. The continuation of this railroad with broad-gage track is called the Bolivia Railway Co., and runs from Oruro, via Viacha, to La Paz. The trip from Antofagasta to La Paz is made in 48 hours. Passenger trains leave Antofagasta for the interior every Wednesday and Saturday at 6:40 p.m. The steamships, as a rule, arrive in the roadstead of Antofagasta in the forenoon of those days, which makes it possible for the passengers to leave by the evening trains for La Paz. La Paz lies in the deep cañon of the La Paz river, about 700 to 800 ft. below the edge of the plateau. At a point above the city is the La Paz Alto station, the terminal of the steam cars. The train is subdivided into sections at this station and taken down the mountain to the city station by electric locomotives. The trains departing from La Paz city station are taken to La Paz Alto in sections, where they are united to form the trains for Viacha and other points. La Paz is a city of 80,000 inhabitants, and has electric power, electric light, street cars, and as good hotels as are to be found anywhere in South America.

Results of the Nitre War

In consequence of the unfortunate nitre war with Chile in 1879, Bolivia lost the provinces on the Pacific coast. While Peru also lost some of the seaboard, and keeps her animosity toward Chile. Bo-

livia has come to an amicable understanding with Chile and made an agreement whereby Chile is to build a railroad from the former Peruvian port of Arica to Viacha on the line to La Paz, and so give another outlet to the Pacific coast. Work trains were running over the whole of this road last year, but the line has not yet been opened to general traffic. Trains will go from Arica to La Paz in 12 hours. Passengers arriving at Arica during the day can leave the same evening and arrive at La Paz the following morning. The third connection of Bolivia with the Pacific coast is by rail from Viacha to Guaqui, a port on Lake Titicaca. Trains from La Paz leave early in the afternoon, arriving at the steamer pier in Guaqui at 6 p.m. Here the train is met by the fast twin screw steamer *Inca*, which crosses the lake and arrives at the Peruvian railroad station Puno at 6 a.m. The journey is then continued across the western Cordillera. At Cruceiro an altitude of 14,666 ft. is reached and the train then speeds down to the port of Mollendo (Peru) making the trip from La Paz in about 30 hours. The Peruvian Corporation, Ltd., of London and Lima, owns the railroad and steamer *Inca*, and has large locomotive and steamer repair shops at Arequipa. The *Inca* has good passenger accommodations. This Company also has a concession from the Bolivian government to improve the Rio Desaguadero by conducting the surplus waters of Lake Titicaca to Lake Poapo. The Company has steamers and barges along this river to collect tin concentrate, silver, and copper, and to carry them to Lake Titicaca and thence to Mollendo. There is also the port of Chilalaya on Lake Titicaca, toward which point can frequently be seen large convoys of llamas, numbering from 100 to 1500, wending their way laden with concentrates. From Chilalaya the concentrates are shipped to the coast by the Peruvian corporation.

River Navigation

By the settlement of the frontier dispute between Bolivia and Brazil, Bolivia received £2,000,000, which sum was used to build a railroad around the rapids of the rivers Beni and Mamore on the Brazilian frontier. These two rivers unite at Villa Bella and form the Rio Madera (Madeira in Portuguese). Near this junction there are 14 distinct rapids which prohibit navigation. These rapids have been navigated by rafts, and although the Indians have acquired much skill in handling them, the loss of life and merchandise is appalling, amounting to between 20 and 50% of the material transported. The tropical climate, together with every kind of fever and other disease, can only be compared with former conditions in Panama. In 1870 a Philadelphia company obtained a concession to construct a railroad around these rapids, but failed. Below the rapids, the river is navigable for large steamers for more than 2000 miles to the city of Para at the mouth of the Amazon river. Above the rapids, the river Beni is navigable as far as Puerto Pando, the railroad terminus from La Paz, and also up the Rios Mamore and Chimore to the railroad terminus of the Oruro-Cochabamba-Chi-

more railroad. This railroad is now finished, and from Porto Velho to Guatara Merrim and Riberalta it is called the Madera-Mamore railroad, and is an American enterprise with headquarters in New York City. The greatest difficulty to contend with in the construction of this road was the climate. The Company has built at Porto Velho a model town and hospital.

Present Railroad Situation

The following table shows the railroad situation at the present time:

RAILROADS IN OPERATION IN BOLIVIA		Miles.
Antofagasta to Oruro (within Bolivia)	574
Ollagüe to Oruro	303
Oruro to Viacha (standard gage)	126
Uyuni to Huanchaca	26
Arica to La Paz (within Bolivia)	273
Caraña to Viacha	125
Branch line to Corocoro	5
RAILROADS IN COURSE OF CONSTRUCTION		
Uyuni to Tupiza	120
Rio Mulatos to Potosi	108
Machamarca to Uncia	52
Oruro to Cochabamba	119
RAILROADS PROJECTED		
Tupiza to La Quiacha	58
La Quiacha to Trajai	131
Potosi to Sucre	106
Oruro to Caraña	189
Cochabamba to Chimore	124
Cochabamba to Vinto	11
Chimore to Puerto Valarde	77
Cochabamba to Arani	45
La Paz to Puerto Pando	158
Puerto Acosta to Rurrenabaque	283
Yacuiba to Santa Cruz	447
Riberalta to Guajara Merrim	66
Guajara Merrim to Velho	145
Porto Velho to San Antonio	5

The outlet from southern Bolivia to the east will be by way of Uyuni, Tupiza, La Quiacha, Jujuy, and Camposanto to Buenos Aires, and as soon as the line from Yacuiba to Embarcacion is built, this road will also be the outlet for the eastern part of Bolivia. Last year the line from Buenos Aires to Santiago was interrupted by snow for three months; passengers and mail had to go from Valparaiso around South America to Buenos Aires. The Argentine line could keep the trains running to the tunnel, but the Chilean line could not keep their end of the road open. The Rio Pilomayo and the Rio Paraguay are large rivers and require but little improvement. They unite at Asuncion and form a continuous water route to Buenos Aires and Montevideo.

Future Outlook

With the completion of the railways which are now in course of construction and the lines which are projected, together with the opening of the waterways, access will be possible to parts of Bolivia which to date have been practically inaccessible. With reduced transportation charges and an outlet to the markets of the world, the mining industry will undoubtedly make great progress and the mineral wealth of Bolivia will attract more attention in the future than it has in the past.

The Magnet Silver-Lead Mine, Tasmania

By P. G. TAIT

*This mine is owned by the Magnet Silver Mining Co., and is situated on the slope of the Magnet range, some five miles from Waratah, on the old Corinna track, which crosses the Pieman 12 miles from the coast, and was the original outlet for the Zeehan field. In its early stages the Company trammed its products to the Corinna-Whyte river road, then carted it to the Emu Bay railway at Waratah for shipment to Burnie on the north of the island. Today the mine is connected with the Emu Bay railway, near Waratah, by a substantial two-foot gage steel tramway, 10 miles in length. It is currently reported that this line, which cost \$144,000, was built from the profits of a rich ore-pocket taken from No. 1 level. The scenery along this line is picturesque, and any visitors to Waratah would be amply repaid if they included this 10 miles in their tour. The railway cuts are studded with berries of various hues, and the fern gullies are really magnificent. The Company possesses two Koppel locomotives, and one by Krauss & Co., all of the articulated type, to negotiate the 99 curves on the route.

The Mine

The top workings of the mine consist of four adits, driven from the eastern slope of the range in a westerly direction, the lode being cut in 40 to 350 ft. of driving. The lode traverses the eastern slope, bearing south 30° west, and consists of a gossan formation from 1 to 30 ft. wide, rich in silver and lead, and carrying a little gold, with dolomite walls. The slate approaches close to the hanging wall on the north end, but is not seen on the south end of the worked portion of the lode. Near the surface the lode was worked by open-cut, and was rich in silver and lead. The Company made large profits out of this portion of the mine. The present workings of the mine are reached from No. 4 level. An inclined shaft at an angle of 20° has been sunk to a depth of 480 ft. The hoisting station is 350 ft. from the mouth of the main adit, and is equipped with a hoist and two Cameron steam pumps. The cross-cuts, of which there are seven, are 65 ft. apart. No. 5, 6, 7, and 8 are depleted so far as the present ore-shoot is concerned, but there is no reason why payable shoots of ore would not be found if the levels were driven south beyond the break or fault which cuts off the ore. The gossan formation, continued down to below No. 7 level in the central portion of the orebody, is being displaced on the north and south ends by dolomite. These levels were also rich in silver and lead, the gold contents diminishing with depth. The greater part of the mine's output is being produced from No. 9 level, which has an approximate ore reserve of 15,000 tons.

The main shaft was sunk two levels, or 130 ft., below No. 9 level, and two stations cut, and the bot-

*Abstract from Mining and Engineering Review.

tom level. No. 11, was driven first, the foot-wall of the lode being cut at 234 ft. from the shaft, when splendid ore was opened. The cross-cut was then continued across the lode until the hanging wall was reached, the lode measuring 60 ft. across. On the hanging wall a fine body of ore was cut 2 ft. in width. Prospecting drifts north and south of the cross-cut are being driven with excellent results, and the manager considers the prospects at this level are promising, and estimates that there is from 10,000 to 15,000 tons of ore in sight. At No. 10 the cross-cut was in 196 ft., and had just reached the foot-wall of the lode. Sullivan machine and hammer drills are used extensively. The air is supplied by a water-driven compressor. Since 1902, 80,500 tons of ore has been exported.

Concentrating Mill

The ore is trammed from the mine and dumped onto a sorting-floor adjacent to a shaking-screen, into which it is shoveled in order to give a more even distribution on the shaker. All pieces below $1\frac{3}{4}$ in. go direct to the mill, the larger pieces being fed onto a picking belt. The first-class ore and clean gangue are here separated, the middling going to a bin, thence to a 9 by 16 Blake crusher, where it is crushed to $1\frac{1}{2}$ in. and trammed to No. 1 mill-bin. From this it goes by automatic feeder to No. 1 shaker. This has a screen with 3-in. square holes to catch any large pieces, chips, etc. All the undersize is fed to No. 1 rolls set $\frac{1}{2}$ in., thence by No. 1 elevator to two lines of trommels screening to over $\frac{3}{4}$ in., between $\frac{3}{4}$ and $\frac{1}{2}$, $\frac{1}{2}$ and $\frac{3}{8}$, $\frac{3}{8}$ and $\frac{3}{16}$, $\frac{3}{16}$ and $\frac{3}{64}$, and under $\frac{3}{64}$ in. The screened ore is delivered to 10 two-compartment Harz jigs, which only make two products. The tailing (and over $\frac{3}{4}$ in.) join at a dewatering screen, $\frac{3}{8}$ by $\frac{3}{64}$ -in. slots, delivering ore free from water to No. 2 elevator, and all the fine and water to a settling-box beneath. The fine is lifted by an ejector to a 3-in. slime pump, where it is joined by the undersize from the trommels. No. 2 elevator lifts the feed to a 100-ton bin, from there by roller feeder to No. 2 rolls set $\frac{1}{8}$ in. Then it goes to No. 3 elevator, and to No. 4 shaker, giving over $\frac{7}{32}$ in., between $\frac{7}{32}$ and $\frac{3}{64}$, and under $\frac{3}{64}$; over $\frac{7}{32}$ in. going to No. 3 rolls, and thence back to No. 3 elevator; between $\frac{7}{32}$ in. and $\frac{3}{64}$ in. to four 5-ft. Bigelow grinding pans, thence to No. 5 shaker. Under $\frac{3}{64}$ in. goes to spitzkasten, where it joins the sand and slime brought up by a 3-in. pump, giving one spigot to No. 5 shaker and the overflow to five single spitzkasten. No. 5 shaker gives over $\frac{3}{64}$ in. and under $\frac{3}{64}$ in., the former going back to No. 3 elevator and the latter to one pair of 30-mesh Callow screens, giving oversize to two single-compartment May jigs, making heads and tailing. The undersize goes to one pair of 60-mesh Callow screens, giving oversize to two Card tables making heads, middling, and tailing; middling returned to No. 3 elevator; undersize of 60-mesh Callow screens to single spitzkasten, giving two spigots of two Card tables making heads, middling, and tailing; middling back to No. 3 elevator, overflow of spitzkasten to five single spitzkasten,

giving one spigot each to five Lührig vanners, making heads, middling, and tailing; middling returned to No. 1 elevator, and overflow to 11-compartment spitzkasten, giving 11 spigots, and overflow to waste: 11 spigots to one single spitzkasten, giving one spigot and overflow to waste; spigot to one Lührig vanner giving heads, middling, and tailing; middling to No. 1 elevator. Dressing water is circulated by a 6-in. centrifugal pump, working at 1400 r.p.m. The ore is intimately associated with the gangue, making it undesirable to discard any tailing until it will pass $\frac{3}{64}$ -in. mesh.

Power Equipment

The mill is driven by three Pelton wheels, working under a 450-ft. head, No. 1 giving 67 hp.; No. 2, 86 hp.; and No. 3, 14 hp. It treats 50 tons per shift of eight hours. There is also a 10-drill Kelly & Lewis compressor, driven by a Pelton, and another for the lighting dynamo. All the Pelton wheels were supplied by local engineers and are giving very satisfactory service. An auxiliary steam plant in two units is available for use during the dry months.

Accretion of gold in amalgamation, according to Allan J. Clark and W. J. Sharwood, consists in the building up of a crystalline layer of comparatively hard amalgam of appreciable thickness, which in extreme cases, as at the Drumlummon mill, may exceed $\frac{1}{8}$ in. If the plate is strained by buckling, or by blows, the brittle sheet of amalgam can be detached in a more or less broken condition, leaving little but the film held by adhesion. Heating over a fire, or the application of steam or hot sand, softens the crystalline amalgam and facilitates its removal by a scraper. In the cold condition it is so hard that it is impossible to avoid gouging into the copper plate when removing it by a steel scraper. Inside plates show accretion to an extreme degree, the amalgam in some cases building up to a thickness of an inch or more. In the case of outside plates such a layer of crystalline amalgam forms an exceedingly efficient, but somewhat expensive, medium for retaining the quicksilver or soft amalgam which is requisite to catch the finer gold from passing pulp. One of the principal objects of electro-plating is to provide a cheaper medium; unburnished electro-deposited silver forms a porous coating easily penetrable by mercury, in which respect it differs from rolled copper. A coat of silver has a minimum thickness of about 0.001 in. for every troy ounce of silver deposited per square foot, but the rough coat obtained in practice is considerably thicker.

Production of raw iron in Germany during May 1913 surpassed all previous records. The total output amounted to 1,641,600 metric tons, as compared with 1,587,300 in April 1913, and 1,492,157 in May 1912. The various sorts produced during May were: foundry pig, 309,892 tons; bessemer, 29,406; thomas, 1,049,524; steel and spiegel, 207,227; and puddle, 45,551.

Coke output of Alabama in 1912 was 2,975,489 short tons, valued at \$8,098,412.

Tailing and Ore Treatment at Broken Hill

*The Zine Corporation, Ltd., operates a flotation plant for treating tailing acquired from mines in the district, and a concentrating plant for treating ore from the South Blocks mine.

Zinc Concentrator

During the year 345,425 tons of tailing was treated, averaging 14.41% zinc, 6.94 oz. silver, and 5.5% lead, yielding 85,354 tons of zinc and 10,881 tons of lead concentrate. These products, at the average prices of metals for the same period, were worth

ZINC CORPORATION'S FLOTATION PLANT.

£449,047. A by-product, in the form of zinc slime, was also saved and stored for future treatment, which, if valued on the basis of a previous sale, would yield £14,989. It is hoped that results obtained from trials of the Horwood process, which indicate an increased revenue from this material, will be achieved on a working scale.

The recovery of metals in the various products was as follows:

	Zinc, per cent.	Silver, ounces.	Lead, per cent.
Contained in zinc concentrate.....	80.9	44.7	...
Contained in lead concentrate.....	..	14.6	32.8
Contained in zinc slime.....	4.8	6.3	4.6

The recovery of lead in the zinc concentrate was 32.8%.

The greatly improved metallurgical work now being achieved is apparent when it is observed that the grade of zinc in the material drawn from the dumps has dropped from 19.1%, the average milled by a former process, to 14.41%, the average for the period under review. The grade of silver is now about 1 oz. per ton less than formerly, while the grade of lead remains the same. Although the material treated during the greater portion of the period has been refractory, owing to many of the dumps being highly oxidized, it is gratifying to record the fact that the grade of zinc and lead concentrates has been improved beyond that for any previous period. The zinc recovery has been maintained, while the distribution of the lead recovery has been improved to the extent that, whereas by the former process the proportions were 40.6% in the zinc concentrate and 29.6% in the lead concentrate, the proportions for the period under review are 32.8 and 32.8%, respectively, a desirable alteration when it is considered that practically no pay-

ment is made for lead in the zinc concentrate.

The year's production of flotation concentrate before being re-treated by 'tabling' totaled 102,355 tons, assaying 43.9% zinc, 13.1 oz. silver, 12.9% lead, equal to a sterling value, based on metals at the average prices for the year 1912, of 69s. 5.2d. per ton of flotation concentrate.

Re-treatment by tabling was responsible for separating this product into:

	Zinc, per cent.	Silver, oz.	Lead, per cent.
85,354 tons zinc concentrate, assaying.	47.2	12.5	7.4
10,881 tons lead concentrate, assaying.	14.8	32.2	57.9

The sterling value of these products was 87s. 8.9d. per ton of flotation concentrate, the enhancement as the result of re-treatment being £93,685. As the cost of re-treatment amounted to £16,089, the profit was £77,596. In addition to the zinc and lead concentrates, a by-product consisting of zinc slime was saved and stored for re-treatment (by the Horwood process); this by-product amounted to 5971 tons, assaying 38.7% zinc, 25.15 oz. silver, and 14.9% lead, and which, valued on the basis of previous sales, less cost of shipping, would realize a further £14,989. The re-treatment operations for the period (including the by-product zinc slime) thus show a total net profit of £92,585. The sulphuric acid plant worked steadily during the period, and produced 4325 tons of acid.

The working costs ranged from 8s. 11d. to 10s. 3d. per ton, the average being 9s. 1.79d., a reduction as anticipated on the average for the previous period. The comparatively high cost of 10s. 3d. incurred in December (the next highest figure being 9s. 3d.) was due to the usual interruption to operations caused by the Christmas holidays: advantage being taken at the same time to effect outstanding repairs.

Plant Construction

Two Babcock and Wilcox boilers, a Bellis Morecom steam-driven air-compressor for supplying compressed air to the mining department, and a British Thompson-Houston 500-kw. mixed-pressure turbo-generator, complete with an up-to-date condensing plant, are being added to the power-plant.

It was found necessary to build extra vats, and so add to the storage capacity of sulphuric acid to hold the extra amounts produced during the winter months, and insure a supply for the mill in the event of a break-down of the acid plant. The total storage capacity is now 470 tons. In order to reduce the distance of belt conveying the residue, and to take advantage of the natural fall of the ground between the zinc concentrator plant and the residue dump, a sluicing and dewatering scheme has been installed, which has effected a considerable saving in belting and power.

In consequence of the favorable results obtained in the laboratory by using the Horwood process on zinc slime, and the results obtained from the 100-ton parcel of ore roasted in the Edwards furnace at Ballarat, Victoria, and afterward treated in the

*Abstract from the annual report of the Zinc Corporation, Ltd.

local experimental plant, it was decided to install a working unit of this process for the treatment of zinc slime. A plant for this purpose is now being erected, and good progress has been made with its construction.

Lead Concentrator

The mill ran 269 days for the period, treating 138,284 tons of ore, or an average of 514 tons per day. The ore averaged 15.3% lead, 2.57 oz. silver, and 9.16% zinc. This tonnage produced 25,227 tons of lead concentrate assaying 6.28% zinc, 9.05 oz. silver, and 67.34% lead, in addition to which 36,800 tons of zinc middling was produced assaying 17.15% zinc, 1.8 oz. silver, and 5.22% lead. At the average price of metals for the year, the concentrate was worth £214,335, and the estimated two-thirds profit on 36,680 tons of zinc middling dealt with by the treatment department, and based on same metal prices, amounted to £19,820. The extractions obtained were as follows:

	Zinc, per cent.	Silver, ounces.	Lead, per cent.
According to lead concentrate.....	..	64.34	80.0
According to zinc middling.....	49.8	19.0	9.1

The extraction of zinc in the lead concentrate was 12.5%, but being of no financial value, is omitted from the above statement. Milling operations have throughout the year given satisfactory results.

The erection of additional tables, storage vats, and connection of the latter with the railway system, has been completed. This has given greater facilities for working, and has enabled the plant to make clean quartz tailing and simultaneously increase the production of zinc middling; the latter product being sent to the zinc plant for further treatment.

Following a number of successful small laboratory experiments with the Lyster selective process (the invention of the mill foreman, James Lyster), a small experimental unit was erected at the lead mill for the purpose of treating a quantity of slime on a working basis. The results obtained from this small unit gave such a profitable recovery of lead and silver that it has been kept in continuous operation, treating the bulk of the current production of slime. A full working unit for the treatment of the current and accumulated slime has been designed, and its erection will be put in hand at an early date.

The 75-stamp mill of the Lake View & Star mines, Kalgoorlie, worked 8028 hours in 1912, crushing 212,606 tons of ore, the duty being 8.47 tons per stamp-day. Concentrate saved amounted to 19,074 tons, yielding 32,715 fine ounces of gold and 757 oz. of silver, while the slime produced, 193,532 tons, yielded 26,396 fine ounces of gold and 5297 oz. of silver.

A hydro-electric power-station is now being equipped at Laufenburg, on the Rhine, which will, when completed in 1914, be the largest plant of its kind in Switzerland. The installation will comprise 10 turbines, each coupled to a 5200-kw. 3-phase alternator, generating 6000 to 6600 volts, to be subsequently raised to 47,000.

Workmen's Compensation Problems

By H. W. GARTRELL

There are two main divisions of mining law; the first is concerned with the acquirement and holding of mineral lands, and the second with the control of mining operations, dealing particularly with the safety of the workmen. A great deal has lately been heard about the first part of Australian mining laws, but the second part is also well worthy of attention.

A very interesting case recently occurred in South Australia. It appears that a man working in a quarry was seen to place a drill in a partly charged hole; his partner struck the drill with a hammer, an explosion followed, and the men were killed. The explosive used was 'raek-a-rock,' which was cut in pieces before being put in the hole. The dependents sued for compensation under the Workmen's Compensation Act.

Summary of the Law

The law may be summarized as follows: (1) The part of the mining law in question applies to quarries on private or Crown lands. (2) An accident is regarded as *prima facie* evidence of the owner's negligence. (3) The general rules, which must be observed as far as reasonably practicable, include: "No iron or steel pricker shall be used" and "In no case shall an iron or steel drill be used for the purpose of drilling out a charge which has missed fire." (4) A mine manager, who contravenes or does not comply with the general rules, is liable to a penalty of \$500, unless he proves that he has taken all reasonable precautions to prevent such contravention or non-compliance. Further, a printed copy of the general rules shall be posted in the office and in some conspicuous place in every mine. (5) The Workmen's Compensation Act provides for compensation up to \$1500, unless there has been serious and wilful misconduct on the part of the workman.

It is interesting to note, though it has nothing to do with this case, that the contraction of lead, mercury, phosphorus, or arsenic poisoning, or of ankylostomiasis is regarded as an accident.

Accepting the supposition that before the hole was completely charged a pebble became jammed in it above the explosive, and that the men were attempting to break this pebble, the discussion first centres on such a procedure. The witnesses distinguished two cases: When the pebble is less than two feet above the explosive, it was generally admitted correct to continue charging and to expect to detonate the first portion of the charge. When the pebble is more than two feet above, four methods were then offered: (1) As above, but one may be permitted to doubt if detonation would often be obtained; (2) to break the pebble by means of half a stick of powder; (3) to drill or jump out the pebble; and (4) to drill a new hole alongside.

The discussion on this interesting contingency seems to have been generally avoided by legislators

and writers. Method (1) may be ruled out; method (3) was said to have been so frequently used by so many, and even when the sides of the hole were almost certainly smeared with explosive, that laymen might reasonably think it fairly safe. Probably most engineers would restrict themselves to the second and fourth methods. The second no doubt answers in many cases; it is quick and simple, but runs the risks of ruining the hole without exploding the charge or of exploding the charge so feebly that little rock is displaced and the face is put in bad shape. The fourth method is safe and certain, but expensive, and probably is little used unless experience has shown that the rock in question is likely to give poor results with the second method. Since one individual's experience of such cases is usually limited, this is a matter on which the experience of others would be very acceptable.

Workman's Position

The next question is, what is the position of a workman who breaks the law? This question was not raised, but probably it may be assumed that a workman is not supposed to know the law unless it is formally brought before his notice, and that if it is so brought, disobedience would be regarded similarly to disobedience to his superiors.

The words "serious and wilful misconduct" naturally offer a fruitful field for discussion. These words occur also in the English act, so naturally the English interpretation bears great weight. Briefly, it may be stated that the word "serious" applies to the misconduct and not to the consequences, and "wilful" is to be taken to mean deliberate and not to apply to acts done on the spur of the moment. From this it follows that unless an act is notoriously dangerous, that is to say, would be regarded thus by most of his comrades in a position to judge, a workman committing it has not been guilty of serious misconduct, and that there is an important difference in seizing a handy tool and going deliberately to fetch a similar tool.

In the case in question, it appears that the misconduct was legally wilful but not legally serious, for the majority of the workmen witnesses said that the act was customary.

Finally, although no appeal was made, it appears that in such a case the higher court would have decided not whether the judgment was correct, but whether the judge might reasonably have found as he did.

The Court's Decision

The judgment, which was wholly in favor of the workmen's dependents, contained several interesting points: "The burden of proving the misconduct, and that the injury was caused by it, is on the respondents, and they must prove it affirmatively and not by surmise. The evidence is conclusive that at the time of the accident the two men were engaged at their work, and it is sufficiently clear that the steel drill was used, but the proximate cause of the accident was not conclusively shown." The importance of this general statement is quite independent of the fact that many mining engineers would regard the proximate cause as conclu-

sively shown. With regard to the fact that no definite rules were laid down and that the method advocated in court was not followed, "The quarrymen had a free hand to use their own judgment, based upon their own experience, and broke no rule," and "If employers require such methods to be followed, it entirely rests on them to make proper rules for enforcing them."

Here then we have a remedial statute designed to help the workman without putting new obligations upon him, and really doing so.

Improvement of Miners' Surroundings

The United States Bureau of Mines is about to investigate the conditions under which a miner works, believing that the unsanitary conditions which exist in some of the mines, as well as in some of the mining towns, are a factor in the death rate among the men. It is intimated that these conditions not only unnecessarily cause the death of miners through disease, but they are often responsible for accidents which might not have happened if the miners were in perfect health.

The Bureau has organized what is known as the Mine Sanitation Section, in charge of J. H. White, engineer, and hopes to bring about progress by appealing to the miner, the manager, and the owner, showing that all three can assist, and be benefited by good sanitary conditions. It will reach the miner by means of illustrated lectures, moving-picture exhibits, and pictorial circulars. These will show how sickness and suffering are spread by careless habits, and will drive home the importance of personal and household cleanliness.

Conditions Peculiar to Mining Towns

Mr. White, in talking about the conditions which exist in mining towns, said: "The mining town does not grow, but is built at a single stroke. The effect of this is that the valuable lessons learned by the 'try-out' method and the profit gained by previous mistakes do not exert their powerful influence, so that the errors existing in one house exist in all; if one house is not properly lighted, none of the houses will be properly lighted; if a few houses are placed too closely together, all houses will be similarly spaced; if there is congestion in one section, there will be congestion throughout. Of course, one could have learned from the experience of other mining towns already built, but this information was perhaps not readily available, and local conditions modify each case.

"One of the first investigations which the Bureau intends to take up is the house problem, with a view to putting before the miners the best practices and the ones which have stood the tests of time.

"The company ownership is the most important factor entering into housing conditions. Every house reflects the standard which the operator wishes to maintain. It is difficult to stimulate a personal pride among the inhabitants, and friendly rivalry is absent. However, if improvements are introduced, they are far reaching, and the tone of

the entire town is raised, so that one house does not point the finger of scorn at its neighbor. The employer being also the landlord means, as a general rule, compulsory payment of rent, and the importance of an assured income should be given due weight.

"In discussing the water-supply situation, it must be kept in mind that the townsite is generally determined by the location of the mine shaft.

"The necessity and importance of a satisfactory water-supply for the people was probably not given much consideration in the past; in studying conditions with a view to introducing a public water-supply into a town, the cost of improvements and the age of the town must be carefully balanced.

"In a limestone region, pollution of the water may come from miles away, which makes the potential danger of the well very great. This may involve the distribution of drinking water in bottles throughout the town, the well water being used for cooking and washing purposes only.

"The inconveniences due to the difficulty of getting water from the wells may be eliminated by establishing bath-houses at mine shafts, so that the men may wash upon coming out of the mine. These bath and change-houses are being widely introduced: in a few states they are required by law. A public laundry is a great convenience for the women, and bath-houses in or near the schools for the women and children are almost necessary accessories to the perfect well system. Wholesome and safe drinking water is essential to existence; its supply is one of the gravest responsibilities accompanying company ownership.

"There are a few mining towns with sanitary sewer systems. Such a system presupposes a public water-supply for flushing purposes. The approximate location of a mining town is determined by the mine shaft, and the topography must be accepted as it is. This is generally rough and hilly, and a single gravity system of sewers is next to impossible, as the cost of leveling off the hills and grading the streets is prohibitive. Moreover, a suitable stream to take the discharge of the sewers might not be near at hand, and the necessity of installing a sewage disposal plant looms up.

"Mining towns possess many advantages, but the drawback lies in the fact that the initiative in maintaining sanitary and clean conditions throughout the mining town rests entirely with the operator. Indifference on his part may give rise to deplorable unsanitary conditions. The residents have no official voice in the government of the town, and unofficial aggressiveness is seldom exerted because the total absence of property rights breeds irresponsibility and carelessness. Many of them are blissfully ignorant of the dangers of unsanitary surroundings, and when they protest it is the inconveniences rather than the dangers that bestir them."

West Virginia, next to Pennsylvania, contains a greater quantity of coking and high-grade coals than any other state.

Several rivers in the Yentna district, Alaska, have their sources in large glaciers.

Reopening the Hillabee Mine

Interesting work in reopening the old Hillabee gold mine, near Alexander City, Alabama, is being done by the Hog Mountain Gold Mining Co., under the direction of H. W. Fox and H. F. Lunt. This property has produced between \$20,000 and \$40,000 per year, or nearly the whole production of Alabama, for the past decade. Hog mountain, on which the mine is situated, is an intrusion of granite in slates, cut by numerous veins of quartz carrying gold. This has been described by H. D. McCaskey in Bulletin 340, United States Geological Survey, to which reference should be made for fuller description. Perhaps a dozen of the veins are of good size. The previous owners worked the oxidized surface ore, treating it by simple leaching without trouble, but were never able successfully to handle the partly oxidized and primary ore with any degree of success. This seems to have been due to lack of metallurgical knowledge rather than to anything in the ore. Recent experiments go to show that by concentrating before sending to the cyanide tanks a good recovery can be made. Inclines are being sunk on two of the veins to determine whether the ore persists in depth. These inclines are being run longitudinally with the veins on a 35° slope, this being the presumable dip of the intrusion. Not enough work has been done definitely to prove the dip. No speed records are being made in this sinking, partly due to the fact that the plant is in poor condition, and partly to the tendency of the natives to live up to their state motto, "Here We Rest."

Before sinking one of these inclines it was necessary to get rid of four or five hundred tons of ore that had been left in a stope above the place where it was desired to begin sinking. This ore had decomposed so that it could not be cyanided, and the process of decomposition had so cemented the pieces together that it was necessary to blast in order to get it out. It was found that enough gold could be saved to pay for taking out the ore by the roughest kind of blanket concentration and reconcentration. This method yielded concentrate containing about 100 oz. per ton. In experimenting with this concentrate, the interesting fact was disclosed that it contains an appreciable amount of bismuth, which is a rare associate of gold in this country. There was also found some coarse gold, an occasional particle being as large as the head of a pin. This doubtless accounts for some of the loss in cyaniding. Particles of gold occur mechanically mixed with what is apparently the bismuth mineral, probably bismuth sulphide, just as sulphides of the base metals occur mixed in a hand specimen. This perhaps indicates why the previous owners claimed that it was necessary to grind to 200 mesh or finer in order to get good extraction. Since the gold is more or less covered with another mineral, it naturally will not dissolve easily. These observations were made on pulp from the tube-mill under the microscope, and as yet the gold and bismuth(?) particles have not been separated in sufficient quantity for analysis, and the laboratory at the mine is inadequately equipped for even the simplest work.

One feature of this work seems to offer great possibilities, namely, the microscopic study of mill products. In fine-grinding practice it is practically impossible to tell by the eye in what condition the gold or other valuable mineral is, after it has been through a tube-mill. Several interesting facts regarding its products at this mine have been learned by the use of a microscope equipped to magnify about 80 diameters. By letting the light shine on the slide from above and cutting off the reflector below the stage, a view of the pulp can be obtained that gives as good an idea of how it looks as could be obtained from looking at material from a coarse jig with the naked eye. This was how the mixture of gold and bismuth (?) above referred to was found.

If the bismuth proves not to contain harmful quantities of arsenic and a market for it can be obtained, it is quite possible that a salable product can be made on a Wilfley table. Most of the bismuth now produced comes from Bolivia, at Huayna, in Potosi, in La Paz, and at Chorolque, in Potosi. The principal region is Tazna, and the smelter is at Chorolque. The price of the metal is controlled by a syndicate and has remained at \$1.60 per pound for many years. Bismuth is also produced in Queensland and New South Wales. Bismuth ores occur in the United States in Colorado and Utah, but there is no present production.

Rock-Drilling Contests

Every Fourth of July these exhibitions of skill take place at the principal mining centres of the Western states, and from the results of the recent contests we have compiled the following record.

At Bisbee, Arizona, the first contest was between three-men teams. They were allowed 15 minutes each, no time being taken out for changing drills or other work outside of actual drilling. The winning team was the Jacobson brothers and Fred Carlson, who drilled a hole 51.9 in. deep in 15 min., winning the prize of \$300. A close second was the team composed of Lawrence Ligon, Joe Hoekway, and Harry Lyons. Their score was 50.9, which took second money, \$150. The boys' team contest was a good one, and great skill was shown by Hooks and Shelp, who drilled 17 in., while Matigan and Densmore drilled 15.9 in. The class of rock used is not stated.

At Cripple Creek, Colorado, excellent work was done in the allotted 15 minutes. Using a 16-V Waugh stopping machine, P. M. Smith, of the Elkton mine, drilled 20 ft. 6.7 inches in hard rock, followed by E. A. Belle, at the Burns mine, with 16 ft. 7 in.; Sid Walherton, with 15 ft. 11.9 in.; Lee Empey, of the C. K. & N. mine, with 15 ft. 8 in.; John Hein with 15 ft. 7.5 in.; and E. Creek and Tom Rogers, practically at tie, with 14 ft. 2.4 in. All machines used $\frac{1}{2}$ -in. air connections, at the end of a 50-ft. $\frac{3}{4}$ -in. hose, while 1-in. cruciform steel was employed. The contest was witnessed by superintendents, foremen, and blacksmiths.

At Globe, Arizona, the contest was one of the best ever held, and about 3000 admirers of the teams gathered around the block. This was rather a poor

granite, which somewhat spoiled the results. There were two close contestants for the first prize of \$250, Zapp and Adams of Globe and Haight and McIver of Miami, closing with only 0.07 in. difference. Zapp and Adams, after losing the first trial by encountering an old hole, captured first prize by drilling 33.16 inches in 15 min. Lundgren and Mills took third prize with 31.62 inches.

At Goldfield, Nevada, the following records were made. Double hand: Rice and Henderson, 52.2 in.; Wickstrom and Jimpola, 50.5 in.; Sikstrom and Schram, 48.9 in.; Trainor and Bannister, 48 in.; Guest and Buchanan, 43.5 in.; Peterson and Adamson, 42.5 in.; and Jonak and Pace, 41 in. Hill and Oist drilled into another hole and were disqualified under the rules. Single hand: Al Billett, 31.9 in.; J. Saxberg, 31.25 in.; Paul Malli, 29.5 in.; Joe Marque, 25 in.; and John Stablum, 19.5 inches.

At Virginia City, Nevada, results were as follows: First prize was won by Harper, who drilled 24.9 in.; second, Grivic, 21.25 in.; and third, Berry, 20.25 in. Time was 15 minutes.

At Tonopah, Nevada, the following results were obtained: A double-handed drilling contest was held, a mass of Rocklin, California, granite being used for the purpose, the following being the result: Page and Johnson, 40.7 in.; Jaleck and Burns, 40.6 in.; and Dahlen and Lindquist, 40.45 in. Last year's drilling records in the same block of granite were: Page and Pickens, 45.45 in.; and Dahlen and Lindquist, 41.45 in. Time was 15 minutes.

The sports at Wallace and Wardner, Idaho, drew large crowds. Nine teams were entered in the drilling contest at the former place, which makes a new record for the number of teams. Perola and Hill of Butte were the winners with 37.5 in. in the 15-min. contest, when their drill stuck and they did not use their last minute of time. Leaf and Morrison were second, with 35.9 in. The other entrants in the contest, with the inches drilled, are as follows: Patterson and Nygren, drilled eight minutes and broke a steel and did not finish; Roseman and Sherwood, 32.5; Spridell and Wurz, 33.3; Fridina and Mara, 32.4; Stokes brothers, 33.9; Siligo and St. Germain, 33.8; and Brady and Haff, 35.2.

The rock-drilling contest was the chief feature of the day at Wardner, and the \$250 cash prize for the first place was won by Siligo and St. Germain, the Stewart mine team. They drilled 46.8 inches in 15 min. This is almost a record in this vicinity, but the rock is reported to have been softer than usual. Two of the teams split the rock while at work, and thereby lost a chance for the money. Sherwood and Roseman took second prize, drilling 42.75 in.

Five teams competed at Baker, Oregon, in drilling 15 minutes in granite. Two teams, George Baker and Albert Dodson, of the Bonanza mine, Whitney; and Andrejs and Dago Joe, from the Buckeye mine, Sumpter, tied for first money, each team drilling a hole 30.7 in. deep. Goodrich and Leroc, from the Columbia mine, Sumpter, drilled 28.5 in.; E. Goddard and A. Porter, of the Ben Harrison, drilled 27.06 in., but had trouble with poor steel; and Johns and Scott, of Sumpter, drilled 26.25 inches.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Colloids in Ore Dressing

The Editor:

Sir—Mr. Caetani's most interesting monograph on sand, slime, and colloids, in the March 22 issue, is a welcome addition to the literature on the subject; and the remarks he makes as to the importance of the question of pulp viscosity are well worthy of attention.

In an article published in the *Mining and Scientific Press* last year on tonnage estimation, I ignored the possible presence of colloids in the system of ore density estimation described, being at a loss to suggest a method of making satisfactory allowance for the alteration of composition due to chemical combination during treatment; or for the difference of density before and after drying. In the same issue there appeared a letter from T. B. Greenfield, giving his experience of the difficulty of obtaining a satisfactory density result in an ore containing a quantity of clay. In replying to this, I pointed out that in most cases tonnage has no significance apart from assay value; and emphasized the necessity for drying the sample for density determination at the same temperature as the corresponding sample for assay. If this precaution is observed there would be no noticeable difference in the theoretical yield as a result of an error, however small, in the density estimation.

Some time later, and in another country, I received my current copy of the *Mining and Scientific Press*, which contained a courteous criticism and a gentle rebuke from T. T. Read on my original article. In this he pointed out that, in the presence of colloids, the method of density determination outlined would give the percentage of ore but not solid in the slime. The loss of water of hydration would account for the difference. On the other hand, I should consider that the action of the electrolyte used would affect the result in the reverse manner. The percentage of solid would be obtained but not the percentage of slime.

Had I the opportunity of seeing Mr. Read's criticism first, I should have amplified my remarks in this direction and would have pointed out that the assay of an ore similarly treated to that of a sample for density determination would also be correspondingly in error. As all *exact* determinations of tonnage are calculated so as to be used in conjunction with assay results, it is obvious that uniformity of treatment before weighing must be observed in each case. On the other hand, if it were possible to make correction in the density estimation to counteract the slight error due to colloidal interference, then a corresponding correction would have to be applied to the assay results.

I would like to take this opportunity of commenting on Mr. Caetani's observations, and to add my agreement to his remarks as to the importance of

de-sliming previous to classification. The ill effects of colloidal matter in interference with the settlement of sand is particularly noticeable in connection with the working of cone dewaterers, which are in some cases used to reduce the moisture of the pulp forming the tube-mill feed, and incidentally to act as classifiers. With a coarse feed, such as when the tubes are merely acting as re-grinders and not as slimers, the cone works fairly well. When all-sliming is practised, and the cone has to handle a fine return in addition to the constant feed, the action is indifferent and uncertain; and any appreciable proportion of colloidal matter becomes entangled with the fine sand, forming a deposit on the sides of the cone which leads to 'piping' through the centre. The result is that the cone works satisfactorily neither as a classifier nor as a dewaterer. No arrangement of vertical or horizontal baffles (whether termed 'diaphragms' or not) will counteract the ill effects of the viscosity of the pulp caused by the inclusion of the finer portions of the ground ore in the feed to the cone.

For a satisfactory method of working such cones, I would draw attention to Homestake practice, where fine screening (900 to 1200 holes per square inch) is used in the batteries, and where the pulp is given two preliminary cone classifications before reaching the dewatering cone, with the result that "the cone remains clear of any accumulation of sand, a rod introduced at the top meeting with no resistance until it reaches the bottom of the cone immediately above the bushing."*

The efficiency of cone feed for tube-mills was made the special subject for remark in the discussion following the publication of a paper on tube-milling, published in the most recent volume of the *Transaction of the Institution of Mining & Metallurgy*.† The attention of members was drawn to the evenness of the cone discharge; and the author's success in working the cone was commented upon. The results were taken as proof that watching and adjustment were both unnecessary; and the impression was created that mechanical separation and dewatering offered no advantage over the method under review.

In the author's reply to discussion and in answer to a request for further information, we find the remark that "the sand issued from the cone in a dry state." The italics are mine, but serve to indicate that the condition of the feed to the tube can be made no subject for comparison or compliment, the cone being used neither as a classifier nor a dewaterer, nor in a manner which could be duplicated in ordinary practice.

The question of internal friction in mill pulp has been ably dealt with by Mr. Caetani in his article. The alternative definition of viscosity is 'stickiness', and it is this characteristic of moist clay which has an important bearing on the working of all apparatus with sloping sides and designed to thicken or classify a colloidal pulp. It is to the 'stickiness' of the clay that the ever-present dan-

*Clark & Sharwood, 'The Metallurgy of Homestake Ore,' p. 26, *Bull. Inst. Min & Met.*, London.

†Ball, H. S., 'The Economics of Tube Milling,' *Trans. I. M. M.*, Vol. 21.

ger of accretion, and eventual chokage of the outlet, is due. As a result, vertical-sided classifiers and thickeners, arranged for the mechanical displacement of settled solids, are becoming more and more popular; and their introduction has marked a decided advance in the progress of the handling and treatment of colloidal ores, insuring a continuity of operation and freedom from attention which was unknown before their adoption.

A. W. ALLEN.

Rhodesia, May 11.

The Microscope in Mining

The Editor:

Sir—In an editorial in your issue of June 7, entitled 'The Microscope in Mining,' you do not give definite reference to an article referring to "a scheme for utilizing the polarizing microscope in the determination of minerals of non-metallic lustre," by A. J. Moses. Will you be good enough to tell me in what publication the article appeared?

D. P. HYNES.

Chicago, June 21.

[We have received so many inquiries regarding the use of the microscope as an aid to mining work that a public reply to this inquiry may prove of assistance to other operators. The paper in question was published in the July number of the *School of Mines Quarterly*, single copies of which can be secured from the publication office, Columbia University, New York City, at 50c. each. Binocular microscopes are much more convenient than the ordinary type for the study of crushed mineral fragments, and hand specimens. The necessary attachment for taking photo-micrographs can be obtained at no great cost, or any ordinary good camera can be used for this purpose with the aid of a little ingenuity. A recent new development is the making of colored photographs, using Lumière plates. In this way the minerals are shown in their natural colors, which is a great aid to recognition. The colored photograph can be studied at leisure and preserved for reference in case later work brings out points which may have been overlooked at first. A little later we hope to publish a detailed description of this work by an investigator who has taken a prominent part in its development.—EDITOR.]

Winter Work in Alaska

The Editor:

Sir—I have read with interest the article in your issue of May 17 last from the pen of W. M. Brewer, on 'Winter Work on the Kanai Peninsula.' There is perhaps no one better qualified to write on this subject than Mr. Brewer, owing to his years of practical experience both in Alaska and the Yukon. In view of that fact it seems almost incredible that you should allow to pass unquestioned the statement made by T. A. Rickard in his otherwise very interesting article in your issue of May 24 on 'The Valuation of Mines.' On page 767 he states: "In some parts of the world, as in Alaska and Yukon, the active season only lasts four or five

months; the period of idleness covering nearly two-thirds of the year," etc. If Mr. Rickard's statement of facts pertaining to other parts of the world are as far astray as those quoted above he will lose any influence he has attained as a writer of credence.

You no doubt have the information at hand without my entering into detail as to the number of days the gold dredges in and around Dawson operated during the year 1912; it is a matter of record. Instead of those dredges operating only four or five months, I think you will find they operated nearly two-thirds of the year. This for placer mining.

In quartz mining there is absolutely nothing to hinder operations the year round in the Yukon, which as a matter of fact is being done right along. If you will look up the records pertaining to the White Horse copper properties you will observe that operations were carried on during the winter of 1912, which, by the way, was the coldest on record in the territory. The Granville Power Co., which obtains its power from the North Fork of the Klondike river, operated during the entire winter of 1912 without the slightest difficulty from anchor ice in the ditch. So far as the company which I represent is concerned, we have not experienced any difficulty in operating and we are at an elevation of 4250 ft. The weather conditions are not one whit worse in the Yukon than they are in certain parts of Colorado, Montana, and Kootenay.

My only reason in calling your attention to this misstatement of facts as they are found in actual practice, is that it has a very bad effect on intending capital for investment in that region. The Yukon will be heard from in the course of a much shorter time than I care to predict. The quartz is there in place in large quantities and undoubtedly rich in free gold.

A. E. GARVEY.

Vancouver, B. C., May 29.

The Editor:

Sir—In reply to Mr. Garvey's protest, I beg to say that the usual season for productive work in the Yukon and in northwestern Alaska is about four months. Last year the Yukon Gold enjoyed an operating season of 172 days (or nearly 6 months) and the dredges worked for 86% of the time, or 5 months. The Granville company worked a part of its plant from April to October, or 7 months. But these two companies are operating on a scale far above the ordinary, and under conditions more favorable than the average. The usual productive period among alluvial mines in that part of the world is, as I stated, about one-third of the year. As to quartz mining, the chief hindrance to continuous operations is the scarcity of gold-bearing quartz veins in the Yukon territory. I am aware of all the facts mentioned by Mr. Garvey, and some others. I see no reason to apologize for making the statement to which he takes vigorous exception. The emphasis was placed on the fact that productive operations in that part of the world are usually discontinuous.

T. A. RICKARD.

London, July 2.

Special Correspondence

NEW YORK

RESULTS AT THE BRADEN MINE.—BRITISH COLUMBIA COPPER CO.—INTERNATIONAL SMELTING HALF-YEAR.—YUKON GOLD OUTPUT.—AFFAIRS OF TUOLUMNE.

Braden made a better showing in June than in any preceding month, 1,808,000 lb. of copper being produced, or at the rate of 22,000,000 lb. per year. In the two mills 61,127 tons of ore was treated, with a recovery of 68.2%. Development work in the Fortuna No. 2 adit advanced 39 metres in 2.97% ore; in the No. 2½, 19 metres in 2.15% ore; and the Teniente No. 1 advanced 12 metres in 2.19% ore. Following the recent announcement of an increase in the ore reserves, this constitutes an excellent 'bull' re-

MAP OF CHILE, SHOWING POSITION OF BRADEN MINE.

port. A special meeting of the Braden stockholders has been called for July 21 to authorize the action of the directors in extending the date of maturity of the convertible 3-year 7% gold bonds from July 1, 1914, to July 1, 1916. There is \$1,000,000 of these bonds outstanding. The mill capacity is being increased to 3000 tons per day, and the need for funds for further development makes this a poor time to redeem bonds. The output of copper of the Braden for the half-year was 8,618,000 pounds.

New financing for the British Columbia Copper Co. will soon be undertaken, according to a statement attributed to Newman Erb. The Company has had a number of British Columbia properties under option, and Mr. Erb states that 1,500,000 tons of ore, up to 3% copper in grade, has so far been developed. If double this amount can be developed, new financing to take these properties over will

be undertaken. The British Columbia Copper Co. now has an issued capital of \$2,958,545. Net earnings last year were \$425,985, and \$177,512 was paid in dividends. The Company is well managed, but its ore reserves are low grade, and it has had a good deal of hard luck in one way or another, and dividends have been few and far between. The Shannon is another hard-luck company. The output for the quarter ended June 30 was only 3,242,000 lb.; the record by months being 1,238,000 lb. in April, 1,080,000 in May, and 924,000 lb. in June. It is announced that work will be confined to the better grades of ore as long as the copper market remains low, but even on a 15c. copper market, Shannon cannot earn dividends, as its operating costs are over 13c. per pound. Like nearly every other company nowadays, the Shannon is attempting to develop a leaching process for the treatment of its low-grade ores. Progress of experiments is necessarily slow, and the outcome is uncertain.

The International Smelting & Refining Co. has had a profitable half-year, earnings, exclusive of depreciation, being at the rate of 15% on its \$10,000,000 capital, and is expected to do even better during the second half-year, as the earnings from new plants should continue to improve. Since its organization, the Company has spent \$4,000,000 on new plants, without issuing new capital, but it is reported that the new smelter which will be built at Burch, in the Globe district, to handle the concentrate of the Inspiration, Miami, Keystone, and other companies, will necessitate the issuing of new securities. The details regarding this new plant seem not to be settled as yet, and there is indeed no hurry, as the Inspiration has not started to build the final mill which is to furnish the smelter with concentrate. In connection with this new construction, Stone-Webster & Co. will undertake the construction of an interurban electric line between Miami and Globe.

The Yukon Gold Co.'s production at Dawson, for the season to June 30, was \$1,015,700, according to a recent report, and for the Iditarod district \$125,400, making a total of \$1,141,100, as against \$1,132,800 last year. The yardage excavated by the Dawson dredges was practically the same as last year, but the value per yard was 70c., as against 76c. for the same period last season, and 66c. for the entire 1912 season. The reconstructed Pacific No. 1 dredge, to be operated on the new properties acquired on the American river, in California, should be ready for operation about the first of November, and this smaller property should, therefore, begin to produce at about the time the Dawson and Iditarod dredges close down for the winter.

At a recent meeting of the Consolidated Coppermines Co. it was voted to issue \$2,500,000 in 15-year 7% bonds, convertible at par, and redeemable at 110, with accrued interest, on any interest day. A considerable amount of these bonds have already been subscribed by the principal shareholders. More than enough of the shareholders in the subsidiary companies have accepted the terms of the merger to give the Consolidated company the necessary physical control, as provided under the laws of Delaware. Another merger, this time at Butte, is to be voted on August 18, when at a special meeting the proposal to increase the capital of the Tuolumne from 860,000 to 1,500,000 shares will be voted upon. The purpose of the increase is to take over the property of the Butte Main Range Mining Co., and efforts are being made to bring the Pilot Butte inside as well. It is reported that the Colusa Leonard Extension may be taken in also. Early in the week it was reported that the La Rose and Nipissing companies had made a joint agreement to take an option in the Plenaurum, at Porcupine. This evoked a vigorous denial from E. P. Earle, who ought to speak with authority. At the meeting of the Chambers-Ferland Mining Co., George Richardson, R. T. Shillington, and Arthur Ferland were elected directors. The basis of exchange between Chambers-Ferland and the Aladdin Cobalt Co., Ltd., shares was not settled, but it is reported that it will be on the basis of one share of Aladdin for 20 shares of Ferland. The output of the Rand mines during June amounted to 747,000 ounces.

BOSTON

ORGANIZATION OF THE MONTANA MINING & DEVELOPMENT CO.—OHIO COPPER CO.'S AFFAIRS.—COPPER PRODUCTION OF CALUMET & HECLA.—NEVADA-DOUGLAS AFFAIRS.—EXPANSION OF THE WOLVERINE COMPANY.

Freeman I. Davison is again at Butte, completing the details of incorporation of the Montana Mining & Development Co., a \$15,000,000 corporation being formed under the laws of Montana. Its object is to develop 140 claims, including the French Gulf mine, in Beaverhead county, and extend a railroad for approximately 50 miles from Divide, Montana, to these new properties. It is understood in Boston that Mr. Davison has associated with him in this enterprise Mr. Allen, the former lieutenant-governor of Montana, Sir Frederick W. Borden, of Ottawa, Canada, and a number of large Canadian, New England, and Western capitalists. The proposed railroad will open an extensive ranching district in the Big Hole Basin country. The general impression here is that Butte Central interests have been largely transferred into the new Company the past few weeks, and it is believed that eventually these transfers will result in the new Company absorbing Butte Central.

Practically the same process is being gone through in exorcising F. A. Heinze from control of the Ohio Copper Co. as was the case in the Davis-Daly company, and not until the purging is completed will Ohio be reinstated in market favor on the Curb here. Recently the annual meeting of the Company was held at Portland, after four postponements in which somebody was apparently jockeying for control, and then no financial statement of the Company was made. This has disgusted Boston people, who see in it some peculiar tactics. Less than a year ago, Ohio stockholders paid an assessment of \$1 per share, and now the stock is selling at not much more than half of that figure, while they are kept in the dark as to the result of operations and the control and management. There is great dissatisfaction expressed at the continued activity of the Heinze methods, and Ohio will be left alone until there is a change for the better. The Mascot tunnel contract has also a retarding effect on the Ohio.

The outputs of the Lake Superior copper mines have been the leading features of interest locally during the past week. The trend of copper prices to a level under the 15c. basis naturally directs attention to the output end of the copper business, and when it was noted that the Calumet & Hecla and its subsidiaries were recording a lower refined copper production than for many months the local coterie was pleased. Calumet & Hecla with its subsidiaries produced approximately 60,000,000 lb. of copper in the first six months of this year, this being a decided reduction from the production of the same six months of 1912, and the lowest record in over four years.

While the sum total of the Calumet properties recorded a loss, the Allouez and Centennial companies were the highest for June in several years. Ahmeek continues to hold well, the largest decrease in production coming from the Calumet & Hecla mine itself.

It was announced here recently that the stockholders of the Nevada-Douglas Copper Co. were to be given the privilege of exchanging 10 shares of Nevada-Douglas for 1 share of Nevada Copper Belt Railroad Co. stock. But first they must be the owners of 188 shares each of Nevada-Douglas to be eligible for the exchange ratio. This works out a value of \$17.50 per share for Nevada Copper Belt Railroad stock, taking the current market quotations of Nevada-Douglas as a basis, and, figured in 'rights' on 188 shares, is equal to *nil*. This works out as follows: Nevada Copper Belt stock was given as a bonus to the purchasers of the Company's bonds. There is no market for the stock now; that is, public market. Nevada-Douglas has a market value of \$1.75 per share. Holders are asked to exchange 10 shares of stock valued at \$17.50 in the market today for a share of stock of the Nevada Copper Belt which has no market value so far as known.

Much interest was aroused by the statement issued by

S. L. Smith, a director of the Wolverine Mining Co., who wants a further expansion of the Wolverine company. This is the first official who has to date committed himself on the subject. The absorption of the Old Colony and Mayflower companies is what Boston expects. At present market prices, Mayflower is selling for a total value of \$600,000 and Old Colony Copper for \$325,000.

TORONTO, CANADA

QUARTERLY STATEMENT OF METAL PRODUCTION.—DEVELOPING THE JUPITER THROUGH THE PEARL LAKE.—MCKINLEY-DARRAGH AND SILVER CLIFF MINES.

Returns made to the Ontario Bureau of Mines of the mineral output of the first three months of the year show an increase of \$2,000,000 in value over the corresponding period of 1912. The total production was valued at \$9,469,938. As the stamp-mills at Porcupine were not in full operation during the first quarter of 1912, no comparison can be made. The principal producers of gold were the Hollinger and Dome. The quantity of ore milled was, in all, 69,905 tons, the average yield being a little over \$15 per ton. The production of silver was 174,485 oz. less, as compared with the first quarter of 1912. Nearly all the output came from the Cobalt mines, South Lorrain furnishing only 198,381 oz., and Gowganda 54,350 oz. Shipments amounted to 7053 tons of ore, 2130 tons of concentrate, and 1,926,150 oz. of bullion. There was recovered by silver refineries in Ontario 2,754,292 oz. The Sudbury mines yielded 1589 tons more of nickel and 538 tons more of copper than during the same period last year. The present producing companies are the Canadian Copper Co. and the Mond Nickel Co., but a new concern which has acquired the holdings of the Dominion Nickel Copper Co. is making active preparations for production. The output of pig iron showed an increase of 64,218 tons in quantity and \$647,901 in value.

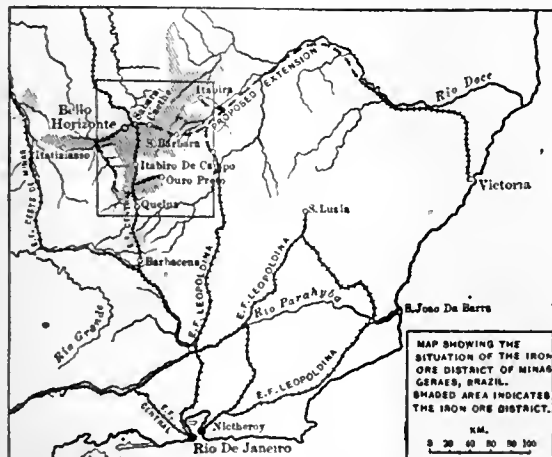

The annual meeting of the Jupiter was held on June 26 when it was announced that an arrangement had been effected with the Pearl Lake, whose property lies immediately adjoining, for the exploration of the Jupiter western areas through the Pearl Lake shaft, by drifts on the 400 and 600-ft. levels. The deep underground workings of the Pearl Lake are close to the Jupiter western boundary, so that mutual economies can be effected from this coöperation in development. Plans for a mill with a crushing capacity of from 80 to 100 tons per day are in preparation, and an electrically-driven compressor has been ordered. The mine has an ore-shoot on the 300-ft. level, 290 ft. in length, averaging \$20 per ton. The Mines Leasing Co. is operating the Rea on a royalty basis and is treating about 18 tons per day with a small stamp-mill. There is 1000 tons of good ore on the surface, and 10,000 tons blocked out underground. At the Hughes-Porcupine, a 10-ft. vein has been cut at the 200-ft. level, and if it opens well at depth a larger plant will replace the 2-stamp mill now working. At the Porcupine Reserve, several good veins have been cut by diamond-drilling.

The May production of the McKinley-Darragh mine, at Cobalt, showed a heavy increase. The output for the month was 206,781 oz., of which 42,662 oz. came from the Savage property. The aerial tramway connecting the latter with the mill is in operation, and the large amount of low-grade ore in the Savage dumps is being reduced by 75 tons per day. The capacity of the mill has been increased, and 50 stamps and 3 tube-mills are in operation, treating 250 tons per day. The Silver Cliff property, now owned by a Toronto syndicate, is opening well, but owing to the poor recovery made, a new mill and six slime tables will be installed. On the Keeley, at South Lorrain, now in the hands of Ehrlich & Hamilton, an English firm, a 3-in. vein of high-grade ore has been opened for some distance. A cross-cut is being driven at the 150-ft. level. The Right of Way Mines, Ltd., capitalized at \$2,000,000, has surrendered its charter and will be dissolved. During June the high and low-grade mills at the Nipissing treated 147 and 6291 tons, respectively, yielding bullion worth \$388,883, having a net value of \$215,418.

LONDON

IRON ORE DEPOSITS IN BRAZIL BEING DEVELOPED BY THE ST. JOHN DEL REY MINING CO.—INSTITUTION OF MINING AND METALLURGY SECURES A PERMANENT HOME.—OFFICE BUILDINGS IN LONDON.

On several previous occasions I have made reference in this column to that celebrated gold mine in Brazil, the Morro Velho, belonging to the St. John del Rey Mining Co. For over eighty years it has been continuously worked by the same organization, and it is now 4900 ft. deep vertically, below the adit. The announcement is now made that the Company is preparing to embark on an iron-ore indus-

try on a large scale. Nothing was said by the directors in their annual report, or at the meeting of shareholders held last month, but hidden away at the end of George Chalmers' (the manager) voluminous report is found a paragraph that appears to be of prime importance. It is well known that the state of Minas Geraes, in which the mine is situated, contains enormous deposits of iron ore, of pre-Cambrian age, and that both English and American iron masters are giving close attention to them. The gold-bearing lodes worked by the St. John del Rey and Ouro Preto companies are found in these iron formations. The iron ore occurs in various forms and grades. On the surface they are mostly fragmental, and of medium and low grade, while below, the ore is laminated or massive hematite of the highest quality. The St. John del Rey company has for the past few years been quietly buying land adjoining the gold mine, and it now owns an unbroken estate of 140 square miles. Development was commenced on one deposit in January 1912, and already Mr. Chalmers is able to estimate the proved ore at 160,000,000 tons, averaging as high as 67.3% iron, with only 0.053% phosphorus. This is covered by fragmental surface ore, of a quality not quite so good. The hematite is soft enough to make mining easy, and at the same time sufficiently hard to make timbering unnecessary in the underground workings. The cost of mining will be low, and the chief item of cost will be that of transport by rail and sea. The Company has no intention of working the deposits in the immediate future, but intends to wait until the exhaustion of the high-grade ores of Spain and the United States creates an active demand for supplies from more remote parts of the world. In any case, it would be impossible to exploit them at present, owing to the scarcity of labor, which even prevents their systematic development. The gold mine is suffering for the same reason, and negotiations are in hand for the importation of laborers from Japan. Railway facilities will also have to be greatly improved. At present they are both insufficient and inefficient. Probably ten years will elapse before progress can be made. In the meantime, the chances are that the gold mine will continue to provide dividends, as the ore reserves contain a four years' supply, and the lode is remarkably persistent.

The Institution of Mining and Metallurgy continues to make gratifying progress. A few months ago I recorded that negotiations were in hand for a royal charter of in-

corporation, the effect of which will give it a legally recognized existence. A further step, of no less importance, has now been taken by the acquirement of a home of its own. Until the present time, the society has had to be content with quarters in one or other office building, first Broad Street House, and lately Salisbury House. The new home is a freehold building on the other side of Finsbury Circus to Salisbury House. This has been purchased outright, ground and all, and a better investment could not be found for the funds of the institution. The building has five floors. The general offices will be on the entrance floor, and the secretary's room and council room on the floor above. The top floors will be occupied by the library and reading-rooms. It is opportune to remind American engineers that nine-tenths of the offices of English mining engineers and mining companies are to be found within a quarter of a mile of Salisbury House. With the development of the London Wall estate, commencing fifteen years ago, the mining fraternity gradually drifted in that direction, from districts round and to the south of the Bank of England. Few of our friends are found nowadays in Cannon and Queen Victoria streets. The last to be left in that quarter is the firm of John Taylor & Sons, who still retain the offices in Queen Street Place close to Southwark bridge. The two handsomest office buildings in the City are London Wall Buildings and Salisbury House. The south sides of these are on London Wall, and their crescent-shaped northern sides on Finsbury Circus. All American visitors should stroll through the gardens in the centre of Finsbury Circus and admire the view across the lawn and flower-garden with the trees on each side and the towers of the two buildings rising above them. We do not boast of sky-scrapers here. For one thing, the light is not sufficiently strong to penetrate into the cañons formed thereby. For another, the ground is not sufficiently dependable, as is evidenced by the anxiety in connection with the stability of St. Paul's Cathedral. We are saved from many heart troubles caused by express elevators. We take things easier, but we get there just the same. The funds for building the two houses I have mentioned came from the diamonds and

SALISBURY HOUSE, LONDON.

gold of South Africa. Wernher, Beit & Co. built London Wall Buildings, and S. Neumann & Co., Salisbury House. The accommodation at the latter consists of 700 rooms distributed over 9 floors. The offices are numbered up to 850, but owing to many numbers being skipped so as to make the century numbers coincide with the floors, the actual accommodation is about 700. Considerable care is taken in accepting tenants, as the reputation of the house is jealously guarded. The Transvaal Chamber of Mines has its London office here. The agent-general for British Columbia is a tenant, though he is shortly to follow the lead of the Institution and find a house of his own. Consulting firms, such as W. R. Feldtmann & Co., and Bainbridge, Seymour & Co., are among the tenants, as are also

mining companies such as the Golden Horse-Shoe and Ivanhoe, and the machinery houses identified with the names of Allis-Chalmers, Wilfley, Hardinge, Deister, and Crompton. I need not add that *The Mining Magazine* is reckoned one of the most respectable of all the tenants.

JOHANNESBURG, TRANSVAAL

THE RECENT STRIKE, ATTITUDE OF LABOR, AND CHANGES OF MANAGEMENT.—MAIN REEF WEST AND CONSOLIDATED MAIN REEF DEVELOPMENT.

A miners' strike on the Rand is rather a unique occurrence, for during the whole history of these fields there has been only one strike of any importance, and the men lost so decisively in that instance that it was generally thought a similar struggle would have been undertaken only after every other resource had failed. However, at the New Kleinfontein mine, owing largely to a want of tact in making a change in the hours of the machine fitters, and a prevailing suspicion on the part of the men against any change in the working hours owing to a recent change in the management, the whole of the white men came out on strike, and at one time threats were made to attempt to involve the whole of the Rand. However, the New Kleinfontein company has, after due consideration, agreed to revert to the original hours, and all danger of the strike spreading has been thereby averted, but as the strike committee is principally composed of professional agitators and socialists, they have been able so far to prevent the men resuming work, on the grounds that the management has repudiated them in arranging the settlement. Hitherto on the Rand, the mine administrations have always refused to recognize the trade union officials in any way, and so far have been able to maintain that attitude, and in this instance, although that attitude has caused a prolongation of the strike, there are not wanting signs that the strike will not extend much longer than a month. This means, however, a loss in profits alone of at least \$96,000 to the Company, in addition to the huge unproductive expenditure a strike usually involves. When the Company gave way, the strike committee attempted to impose new and more onerous conditions in the shape of an eight-hour day from bank to bank, instead of from face to face, as legalized in the Transvaal. Such an innovation would have imposed a heavy burden on the mines, with their constantly growing depths and areas of operation, and it is fortunate that the New Kleinfontein miners have not responded to the innovation. The lesson taught by this strike is the growing need of tact in attempting to make changes in working hours, and generally to recognize that, on the Rand, there is a strong feeling against the numerous and often unnecessary changes made in the management. Up to the present these changes often have involved a complete change of staff, with new ideas and a tendency to attempt to lower the working costs, before the new administration has obtained a proper insight into the actual conditions prevailing in the mine.

Among the mines on the Rand, there are few that have given so much cause for anxiety owing to the large proportion of unpayable ore developed, as the Main Reef West. At one time this mine was regarded as one of the most promising mines on the Western Rand, and shares were bought in usually well informed quarters at high prices. Since then the shares have fallen to the extent of one-eighth their former value, and the development record of this mine for the last quarter is indeed a most unsatisfactory one. Out of 3434 ft. of development, 2386 ft. was on the 'reef,' but, of this, only 931 ft., or 39% of the whole footage, was found to be profitable. No less than 2386 ft. was found unprofitable, only showing an assay value of \$3.30 per ton. The property, however, is an extensive one, and there is every probability of another profitable area being soon discovered, while the mine is far from being in difficulties, as the present developed profitable ore reserves already amounted to 633,610 tons. While the Main Reef West property has deteriorated to this extent, its neighbor, the Consolidated Main Reef, has im-

proved, so that sooner or later there is every reason to look for an early change for the better in the Main Reef West also.

BUTTE, MONTANA

THE DRUMLUMMON MINE.—ANACONDA COMPANY'S BELMONT SHAFT TO BE MAIN ORE OUTLET.—TUOLUMNE COPPER CO.'S AND BUTTE MAIN RANGE PROPERTY.

Now that the protracted and bitter litigation between the St. Louis and the Drumlummon interests has been brought to a final close, the St. Louis Mining Co. is beginning to look about for some use to make of its hard-earned possessions. A new cyanide plant has been built, and prospecting is under way at both properties, so as to keep them running. The best ore has been mined, but shoots containing a good tonnage of cyaniding ore undoubtedly await development. In the meantime, the pioneer owner of the Drumlummon is successfully operating nearby properties, and proving to those interested in the district that his successes are not altogether due to luck.

Butte, like most mining districts, is all the time struggling with a few 'lame ducks' which were born in good faith and with high promise, but whose injuries come about from inability to find ore in sufficient quantities. Among such at present are the Raven Copper Co. and the Davis-Daly Copper Co. In both of these properties, conscientious and intelligent efforts have been made to develop paying mines, but the orebodies seem to be wanting. The only complaint to be made is that the true speculative features of such conditions are frequently concealed by promoters, and many Eastern people invest under a wrong impression as to the chances involved. Raven copper, for instance, seems to have done nearly enough work to prove that it is not a mine, and the discouragement of the stockholders is being reflected in the sagging of the stock.

Many of the shafts of the Anaconda Copper Mining Co. are situated high on Anaconda hill, several hundred feet above the level of Silverbow creek. Ore through these shafts is hoisted to the top of the hill and taken down again by way of the surface trains. This wasted energy is appreciated by the Company, and it is planned to obviate it to some extent by making the Belmont, at the foot of the hill, the chief ore-producing shaft in the future. Electric trains on the different mine levels will deliver the ore to large skip pockets at the Belmont shaft. Of course, no one shaft can handle the ore and supplies for all of the mines, but it is, nevertheless, expected that ore-handling at the Belmont will effect a large saving.

The Tuolumne Copper Co. is considering the acquiring of the burdens of the new Butte Main Range Mining Co. An attempt was made recently to finance Butte Main Range independently, but, it would seem, with indifferent success. It is now proposed to increase the capital stock of the Tuolumne company from 800,000 to 1,500,000 shares, with a view to raising money to develop Butte Main Range. It appears that the Tuolumne will have its hands full with its own and the proposed business. Butte Main Range may prove to be a big mine, but it seems too bad for a good little mine like the Tuolumne to run the risk of adding to its burdens the prospecting of a new property in an admittedly unproved part of the district.

SILVERTON, COLORADO

DISPUTE BETWEEN THE TONOPAH AND CONTINENTAL MINING COMPANIES OVER TITLE TO THE BUFFALO BOY MINE.

The trouble between the Tonopah Mining Co. and the Continental Mining Co. is rather strange, and it is hard to get much data on the subject. The facts, as nearly as can be gathered, are as follows: Last fall, D. M. Haines came into the San Juan and began taking options on properties along the so-called Eastern gold belt lying to the south of the Animas river, its best known mines being the Highland Morn, Shenandoah, Dives, Old Abe, Buffalo Boy, Intersection, Esmeralda, Trilby, Kittmac, and others of less importance. Mr. Prosser, during his services

as secretary of the Silverton Commercial Club, had spent much time in a study of this region, and was selected by Mr. Haines as his assistant, and still serves in that capacity. Most of the options, it is understood, are in Mr. Prosser's name. The Continental company owned the Buffalo Boy, and had spent about \$30,000 on development, and claimed to have opened ore, averaging \$19 per ton, over a distance of 1200 ft. in the main adit. The property was examined about a year ago for the Mines Company of America, but for some reason the deal fell through, although it is rumored on fairly reliable authority that this Company estimated the value of the property to be \$600,000. This is, of course, doubtful, but the value of the ore is nearly correct. Mr. Haines bought the Old Abe, or at least a controlling interest. This property adjoins the Buffalo Boy. Mr. Haines then attempted to buy the stock of the Continental Mining Co. at 38c. per share, the controlling owners, Martin Heller and Joe Bordelean, holding out for 52c. per share, which Mr. Haines refused. Mr. Haines then bought the stock of A. A. Brown at a rumored price of \$30,000, this stock consisting of a one-sixth interest in the Company.

In January, while the Continental company was actively at work on underground development, Mr. Prosser relocated all the Buffalo Boy ground in the name of Mr. Belford, and served notice on the mine superintendent, Ed. Haas, that he was a trespasser, and to vacate the premises at once. Mr. Haas, of course, refused to do so, and is still in possession. The exact grounds for the re-location are not known, some claiming that the original locator was not a citizen, others that the Buffalo Boy locations are on other claims and are invalid. The strange part of it is that Heller and Bordelean should hold such a valuable property without a patent for six years. It was, however, surveyed last summer, and an application for patent is now before the Surveyor General. Local feeling is divided, the majority favoring the Continental company. It seems as though Haines and Prosser hope to force this Company to settle on their terms, but at the same time the title is bad. Mr. Haines has a right to protect the Tonopah people, as it is rumored that their total investment in the Buffalo Boy and vicinity amounts to \$110,000. The Continental people were the makers of this mine and have held it in good faith for six years. However, their way of doing business seems to be a poor one; and if they lose the property through a faulty title, they have only themselves to blame.

BRITISH COLUMBIA

MINING ON THE NORTHERN COAST.—HISTORY OF THE HIDDEN CREEK PROPERTIES DEVELOPMENT.—PORTLAND CANAL TUNNELS, LTD.

The purchase in 1910 by the Granby Consolidated Mining, Smelting & Power Co., Ltd., of the mineral claims on Observatory Inlet, Portland Canal, assured for that portion of the province operations of such magnitude as would place it in a prominent position. The history of this Hidden Creek property is quite interesting, because of the fact that it just escaped being numbered among the abandoned prospects that are to be found in every mining camp on this continent. In 1900, M. K. Rodgers bonded this group of claims from the original owners, Flewin and Rudge, of Port Simpson. Mr. Rodgers at that time was acting for the late Marcus Daly, and after Mr. Daly's death the executors had examinations made of all his mining properties, including those taken up for him by Mr. Rodgers. Chief among these were the Nickel Plate mine at Hedley, and this Hidden Creek copper property on Goose bay, now known as Granby bay, Observatory Inlet. The result of this examination was that, although about \$15,000 had been expended on the property, it was ordered abandoned, and reverted to the original owners. Later, about 1906, the group of claims was bonded by a Vancouver syndicate on the same terms, namely, \$40,000 purchase price, as had been given to Mr. Rodgers. This syndicate expended altogether about \$20,000, and in February 1908 the property was again purchased by Mr. Rodgers for himself and

Thomas Hudgins of Butte for \$135,000. These gentlemen continued development on the mining claims, constructed a tramway, wharf, camp buildings, developed water-power, and erected a power-house. They also located some adjoining ground, expending thereon quite a large sum of money, and developed such extensive copper ore reserves as to be able to sell the property in 1910 to the Granby company for about \$500,000.

At the end of June there were 1125 men on the Company's payroll at Granby bay, most of them being engaged in general construction work. The smelter and converter plant will be completed and in operation about the first of next year and will have a treatment capacity of 2000 tons per day. The mine is now sufficiently developed to ship that quantity of ore daily, it being estimated that there is over 8,000,000 tons of ore in sight. The difference in the elevation between the upper exposures of ore on the mountain, and the lowest of a series of adits is 865 ft., and

SITUATION OF HIDDEN CREEK COPPER MINES.

between the upper exposures and the deepest diamond-drill holes sunk to a point 300 ft. below sea-level, there intervenes a vertical depth of approximately 1500 ft. This will serve to convey some idea of the area of ground that has been proved to be ore-bearing. The last cores of mineral taken from the lowest diamond-drill holes gave assays of 6 and 11% copper.

Stewart has experienced quite a slump, and at present, except for the work being done by the Portland Canal Tunnels, Ltd., of which W. J. Elmendorf is manager, there is little activity, as the investing public is waiting for the results from the adit being driven by that Company. The proposed length of this adit is about 2300 ft., and from the direction in which it is being driven it will cross-cut the ground owned by the Glacier Creek Mining Co., the Stewart Mining & Development Co., and the Portland Canal Mining Co. In the last named property this adit will cut through at a depth of about 2000 ft., below the present workings on the Portland Canal mine. The present face of the adit is about 1800 ft. from the portal, and it is expected that it will be completed about November. The future of the 'camp' to a great extent hangs on the completion of this work, and if the orebodies are found at this level, the success of the district is assured.

General Mining News

ALASKA

The unexplored islands of the Aleutian group will be examined for mineral deposits by George A. Parks, who is employed by the United States Land Office. Of the territory to be explored, Akun is on the western shore of Unimak pass, in the Krenitzin group of the Aleutians. Akutan is the largest island in the same group, and is situated northeast of Unalaska.

FAIRBANKS

A good deal of drilling is being done on Ester creek, but results so far have not been published. On June 11 the Chatham property changed hands. Work is proceeding steadily and the 4-stamp Hendy mill is running. Quite a number of miners are sluicing on Deadwood creek, in the Circle district. According to reliable reports, the Red Mountain district of the Koyukuk should produce \$50,000 in gold this season, or about twice as much as in 1912. In the Ruby district, the Ferry Bros. are the only ones who have done extra well. At the spring clean-up they recovered \$18,000 from their dump. On Long and Poorman creeks a good deal of prospecting is being done.

JUNEAU

(Special Correspondence.)—The Sheep Creek adit of the Alaska Gastineau Mining Co. was advanced 570 ft. during June, and for 10 days a speed of one foot per hour was maintained in good ground. The adit is 8 by 10 ft. Three shifts are working. P. O'Neil is foreman and B. L. Thom superintendent. A new dam will be built at the Nugget creek power-site of the Alaska Treadwell company. A sample of one ton of ore from the Kensington mine has been shipped by B. B. Neiding, the superintendent, to the Merrill Metallurgical Co., San Francisco, for testing purposes. Juneau, July 3.

ARIZONA

COCHISE COUNTY

The Gus Baron group of zinc claims in Montezuma cañon, in the Huachuca mountains, have been bonded to a group of Tennessee capitalists. The first payment has been made and development of the property will begin shortly. This property was at one time leased to the Mitchell Development Co. The new mill of the Commonwealth Mining & Milling Co., at Pearce, will be ready to operate by August 1, according to H. J. Rahilly, who has been supervising its construction. The mill has 30 stamps, three Hardinge mills, and three tube-mills, Pachuca tanks for agitation, and four Dorr tanks for settling. The pulp is then run through four Oliver continuous filters. The mill will treat about 350 tons of ore per day.

GILA COUNTY

At the Miami mine, good progress is being made in re-opening the caved ground. During June, development totaled 7285 ft. A good deal of work is being done at the Captain shaft. Underground work at the Inspiration has slackened of late, and in June this covered 2600 ft. It was necessary to cement the drill-hole at the Southwestern Miami in order to recover a string of tools. A 40-ft. head-frame and 25-hp. gasoline hoist has been erected at the Inspiration Extended.

MOHAVE COUNTY

On July 11, four bars of bullion, valued at \$99,500, were shipped from the Tom Reed mine to Pasadena, California. This gold output was the clean-up for June from the 30-stamp mill. The Gold Road shipped gold worth \$20,000 on July 10, this being a clean-up for the first week in July.

George W. Heintz, general manager for the United States Smelting, Refining & Mining Co., recently inspected the Gold Road mine. An average of about 50 tons of ore per day is being treated. If mine conditions warrant it, the Company proposes to raise the mill capacity to at least 500 tons per day. Mining operations are being carried on much the same as they have been since the property was

acquired. The ore sent to the mill is coming from the upper levels and a goodly portion of it from the 500-ft. level. The drift from the lowest workings has cut the ore in stringers and bunches, and a raise is now being driven toward the shoots higher up.

PINAL COUNTY

(Special Correspondence.)—The old Mammoth-Collins mines, at Schultz, which for many years were the chief factor in the prosperity of so many people in that part of the county, have changed ownership, and hereafter will be operated by the Young Bros. of the Great Western Copper Co., of Courtland. They will put the mine workings in a good state of repair at once, then proceed with development on the 800 and 900-ft. levels. Later on, the mines will be equipped with more modern machinery, including a new reduction plant. The property has produced several millions in gold, and the new owners believe that they can be made to duplicate the past record many times over. Below the 800-ft. level the vein on the Mammoth ground is about 30 ft. wide, and averages about \$9 gold per ton and from 4 to 6% copper.

Schultz, July 10.

YAVAPAI COUNTY

Operations have been resumed at the old Waddell group on Copper creek, in the Hassayampa district. About 50 ft. has been driven in the old adit, in a continuous shoot of copper ore. Attention is again being attracted to the placer mines of Sam Norlan at the Three Mile house, on the wagon-road to Walker. According to reliable reports, the ground is reputed to be rich. In work performed recently it is believed the original channel has been opened.

CALIFORNIA

ELDORADO COUNTY

The Channel Bend mine, on the Forest Hill divide, in former days called the Eagle Bar, and at one time very rich, is to be reopened and tested by local people, among whom is N. L. Kohn, who for several years has been endeavoring to bond the property and has only recently been able to secure an option on it. Last week the first load of supplies and prospectors left for the 'North Side,' among them Fred Hoskins, and Irving and Lee Cohn, who will start development work.

GLENN COUNTY

L. N. Comstock and B. L. Dyer, of Fresno, and H. Horn, of Willows, have been leasing oil land for some time and have obtained options on upward of 10,000 acres. At the same time J. T. Leland, who is declared to be a representative of the Standard Oil Co., arrived on the scene and took a number of options. All the land leased is in the vicinity of the Butte ranch, west of Germantown. The Butte ranch is owned by Frank Freeman and associates. It is said that Comstock and his partners got the ranch option. Some months ago oil was found in a deep well on the ranch, and promising sands were found. A test well is to be sunk in a few weeks.

KERN COUNTY

(Special Correspondence.)—A carload of copper ore has just been shipped by Joseph Weringer from his Greenback mine to the Selby smelter. He has only recently reopened the property.

Woody, July 10.

NEVADA COUNTY

Suspension of work at the Gaston mine, in the northern part of the county, was only temporary. The 10-stamp mill is being moved to a position on Porman's creek below the lower adit, which is in 4000 ft. At the Erie, near Graniteville, 35 men are employed, and the stamp-mill is in full operation. At the Ancho, Birchville, and Republic the mills are also crushing good ore.

PLACER COUNTY

Three carloads of machinery have been received for the Guggenheim mines at Mammoth Bar, recently purchased by these interests. Buildings are being erected and work has been commenced on the dredge. Representatives of

the Guggenheims are investigating various bars along the American river, and it is likely that Poverty bar, near Butcher ranch, will be purchased by them in the near future. A full force of men is working in the Bullion and Grass Ravine mines at Ophir. A drift is being run on the 400-ft. level of the Bellevue into the Bullion ground, and is now about 30 ft. below the old workings. Another drift from the same level is being run into the old California ground. Machine drills are being used in both drifts. The 80 tons of ore from the Bellevue which were run through the mill of the Big Busar company gave good returns, and another lot of 50 tons from the Grass Ravine mine was crushed last week. The mill at the Crandall has been repaired and is again crushing ore from the mine. About 25 men are working at the Black Canyon mine around the sawmill and in road-making and getting the mine in shape to commence development. The people who are working the black sand at the Mayflower, near Forest Hill, have installed a new gas-engine. It is much larger and more powerful than the first one, and it is hoped that the Company will be soon grinding the sand.

SHASTA COUNTY

The Hayfork Mining & Milling Co., composed of people of this county and Oregon, has leased its property at Harrison Gulch to C. A. Mueller, of Redding. He is driving a long cross-cut to intersect the extension of the Midas vein system. A rock-crusher will be installed at the mill. At the Murphy-Layman mine, in this district, a 4-stamp mill is crushing good ore.

SIERRA COUNTY

The Telegraph gravel mine is temporarily closed until arrangements are made for regular operation. At the Sierra del Oro (Ironsides) the men are opening an old adit and will extend it to the ore-shoot. The old adit is already in about 200 ft., and by driving 300 ft. more they can develop the rich shoot 100 ft. deeper than has been done heretofore. H. B. McCormick is manager. The shoot opened in the Uncle Sam or North Fork, at Forest, is said to be showing free gold and arsenical pyrite, and prospects are good.

It is stated that the old Ruby gravel property, near Forest City, is to be reopened. Oakland people have an option on it, and if on examination is satisfactory, will probably buy it. The Ruby has a large acreage of lava-capped ground and was worked extensively in the early days through a long tunnel tapping the channel at 2200 ft. in from Rock creek near the northern boundary line of the Bald mountain. It was mined the full length of the claim and then abandoned. Since then it has passed through several hands, until the present people took an option.

TUOLUMNE COUNTY

(Special Correspondence.)—The Atlas mine, at Tuttle-town, has been purchased from Fred Sutton by J. L. Witney, representing the company that has extensively developed the property during the past year or more. The mine was previously deeded to Mr. Sutton by Robert R. Morrison, of San Francisco. Mr. Witney has also secured an option on 40 acres of mining land adjoining the Atlas from Ferguson McArdle. The renewal of activities at the Atlas is expected soon.

The Wagner Mining Co. has acquired the Paymaster group of three claims, situated south of Tuolumne, and is vigorously carrying on development work. The Paymaster vein, which was opened by adits, aggregating several hundred feet in length, by the original owner, Andy Omodt, ranges in width from 3 to 12 ft., and assays indicate that the ore will give mill returns averaging at least \$10 per ton.

Sonora, July 12.

The old Dutch mine, at Quartz, is having considerable equipment installed, while in about two months it ought to be free of water. John Segale and associates are preparing to construct a large dam and excavate a ditch above the Clfo mine to turn the river from its natural course, and the work will be rushed to completion before the heavy fall rains set in. It is expected that a good deal of gold will be recovered by working the old river bed.

COLORADO

EAGLE COUNTY

(Special Correspondence.)—The Lady Belle mine has shipped its nineteenth car of ore, averaging over 100 oz. silver per ton. The mine is opening well. There are several prospecting parties in the district.

Eagle, July 14.

The *Eagle Valley Enterprise* states that an interesting mining project, adjacent to Eagle, is the draining of the lake at the headwaters of Lake creek. The object in view is placer mining the 80 ft. of deposit of wash in the bottom of the lake. Samples of the wash run as high as \$13 to \$20 per cubic yard. In order to drain to the bottom of the deposit, it will be necessary to drive a 900-ft. tunnel

MAP OF EAGLE DISTRICT.

from below. Work is being done at present on this project. Edward J. O'Flaherty has charge of the operations for the Electra Gold Mining Company of Denver.

GUNNISON COUNTY

The Tin Cup Gold Dredging Co., a newly organized Denver concern, is erecting a dredge at Taylor Park, which should be ready in about 60 days. The Company owns 1900 acres, and will build two more dredges if results are satisfactory. The new machine is 45 ft. wide and 85 ft. long, and will weigh 150 tons. The ground has been properly tested by drilling, which proved bedrock to be 35 ft. deep. W. B. McDonald is in charge of the dredging work.

LAKE COUNTY (LEADVILLE)

The Western Mining Co. is practically the only property shipping carbonate of zinc ores at present, and only large operators can afford to produce it, according to S. D. Nicholson, manager for the Company. The drainage of Fryer and Carbonate hills is being arranged, although both will be separate propositions. Work in the lower adit of the Mt. Champion is opening a good deal of ore, and the mill is working regularly. Gold and copper ore has been opened in the Eureka in a raise above the adit. The Bertonell lease at the Little Jonny shaft No. 4 continues to produce rich ore. A recent sampling of the shoot returned 484 oz. silver, 11 oz. gold, and 5% copper.

Birdseye, Alicante, Big and Little English gulches, and French gulch lately have witnessed an influx of prospectors, or owners of small claims, who have started to do the annual work for the year on the different claims. Some prospectors are working toward the head of the different gulches looking for mineral alongside of the big porphyry dike that trends through that part of the country, and the same that comes from the famous Little Jonny, Breece hill. Interest in Lackawanna and Half Moon gulches becomes more apparent each week, as reports from these districts state that prospectors can now be found scattered over the different hills and gulches. They have all found

float which yields from a few dollars up to 3 and 5 oz. gold per ton, and a search is being made to find the vein from which the float came.

The Pyrenees Consolidated Mines Co. is increasing its capital from \$100,000 to \$250,000. The old mill of the Leadville public sampling works is being overhauled and repaired, to make a test run on zinc ore from La Plata and other shafts in the neighborhood.

OURAY COUNTY

No. 7 level is now being driven from the Camp Bird shaft, which is down 800 ft., and will probably cut the vein in about 150 ft. Three shifts are extending No. 5 level of the Humboldt north toward the mountain top. A contract is to be let for sinking a further 125 feet.

SAN MIGUEL COUNTY

The Junta Consolidated Gold Mining Co. owns 20 claims on Ballard mountain and La Junta basin, south of Telluride. At the former section, an adit has been driven 1450 ft. on a vein, averaging \$12 per ton over 7 ft. In the Junta group several adits have been driven. About 300,000 tons of ore is said to be opened, and a 300-ton mill is being erected. A 3000-ft. tramway has been constructed to the mill. T. E. Thomas, of Telluride, is in charge.

TELLER COUNTY (CRIPPLE CREEK)

During May, Stratton's Independence mine produced 4624 tons of ore on company and lessees' account, while the mill treated 11,800 tons of dump ore, resulting in a total profit of \$10,325.

MONTANA

FERGUS COUNTY

During May the Barnes-King Development Co. mined and milled 3895 tons of ore from its North Moccasin property at Kendall. Mining and milling costs were \$3.50 per ton, a total of \$13,632, leaving a balance of \$19,002, of which \$14,252 was paid on the North Moccasin property and \$4750 retained by the Barnes-King company. From December 14, 1912, to May 31, 1913, the Company mined and milled 18,897 tons of ore, averaging \$8.70 per ton and having a gross value of \$164,418.

LEWIS AND CLARK COUNTY

The East Helena smelter has a large district to draw upon for ore, and its supplies are likely to be increased by opening old mines. The Dobler property, 15 miles east of Helena, is to be reopened. The shaft is in swampy ground, and is flooded, but the vein opened was profitable, so pumps are to be installed. The Eureka, 12 miles from Helena, is also to have a new pumping plant. It is under bond to the Anaconda company, and it will be developed to 500 or 600 ft. The Fisher claim is opening well. The Montana copper-silver mines are opening in a promising manner.

LINCOLN COUNTY

(Special Correspondence.)—The Vermillion Silver & Lead Mining Co. is developing its claims in the southern part of the county, and it is intended to begin shipping ore soon. The main adit being driven on the vein is now in a distance of 500 ft. The ore contains gold, silver, and lead. The Mountain View Mining Co. is installing a 6-drill air-compressor on its property, 40 miles south of Libby. The main adit is in 1400 ft. and will be continued until it cuts the four veins in the claims. The ore is said to be rich in gold. The Company owns twelve claims. S. F. Ralston came in recently from the Kalispell-Lincoln Gold Mining Co.'s property, bringing with him \$1000 in gold that had been cleaned up after a short run with the small 5-stamp mill. Most of the machinery for a concentrator and an additional five stamps has arrived at Libby and will be taken to the mine and erected. Latest reports from the Shaughnessy Hill mine, which is being developed by the Hazel T. Mining Co., are to the effect that the drift is in an orebody 15 ft. wide, containing mostly silver and lead. The Company proposes erecting a concentrator.

Libby, July 12.

SILVERBOW COUNTY

(Special Correspondence.)—Development is still being

done on the 1900-ft. level of the Raven mine, and while some ore is between 3 and 4% copper, there is not sufficient yet to pay the operating expenses. However, the management still believes that a large body of good shipping ore will be opened, and with that object in view the work is being done.

The Butte & London property, which has been idle for the past six years, will be reworked in about 60 days. The electric equipment has been ordered, and it should be delivered about the middle of August. The power has been arranged for and as little delay as possible will occur after the machinery arrives. The mine is to be operated by the Rainbow Development Co. under an agreement that the shaft will be carried from its present depth of 1100 ft. to 1660 ft. When the property was closed during the panic of 1907 there was every evidence that some good ore was about to be opened, but conditions were such that it was deemed advisable to quit work, and later the directors sold the machinery. The Rainbow Development Co., which is controlled by Duluth capitalists, has a shaft down to a depth of 680 ft. It is operated by electricity. E. C. Congdon is president of the Company, and Thomas F. Cole is a member of the board of directors. According to reports, the Colorado mine produced 7250 tons of ore, during the past month, averaging 3.4% copper and 6½ oz. silver per ton. The force of men has been increased, and development is being done on the 1700 and 1900-ft. levels.

Butte, July 13.

The new surface plant on the Gambrinus claim has been completed and active development work by the Corbin Copper Co. on its group of claims adjoining the Gagnon mine is now well under way. The plant has capacity for sinking to a depth of 1500 ft. Compressed air is used instead of steam for motive power, and is generated by an electrically operated compressor. The Gambrinus shaft is now down to a depth of about 50 ft., and is of three compartments. The future appears to be exceptionally promising.

NEVADA

CLARK COUNTY

(Special Correspondence.)—Seven feet of ore carrying 10% copper and \$18 per ton in gold has been opened at the Duplex, on the 700-ft. level, 225 ft. from the portal. This ore was not expected, as the drift was driven to cut the New Year's Gift vein. At the Quartette, the 1100-ft. level, west of the main shaft, opened free-milling ore with a little copper. Ore shipments continue from the Southern Nevada, Fourth of July, Chief of the Hills, Bamberger-Wheatley, Blossom, Duplex, Good Hope, and Quartette leases to the mills, and in some cases show an increase of tonnage. The June production of the district was valued at about \$61,400.

Searchlight, July 12.

ELKO COUNTY

(Special Correspondence.)—The drift, at a depth of 53 ft., in the winze of the Flaxie mine, has opened another rich shoot showing gold. Work is to be started at the Alpha in cutting a station and installing a hoist at the junction of the adit and shaft, at a depth of 250 ft. At the Success, the cross-cut is in 100 ft. in hard rhyolite. The upper adit of the Jarbidge-Altitides is in 30 ft., showing 30 in. of rich ore, while the lower adit is in 330 ft., but has not yet cut any ore.

Jarbidge, July 7.

ESMERALDA COUNTY

Preliminary estimates of the Goldfield Consolidated company's June output show the treatment of 30,308 tons of ore yielding \$361,000. The 1750-ft. station in the Merger is finished, and cross-cutting is under way to the Atlanta. The Vernal is shipping ore varying from \$42 to \$55 per ton.

LYON COUNTY

The Adams gypsum mine and plant at Mound House is working three shifts, as the Pacific Portland Cement Co. has a contract with the San Francisco fair authorities for 3000 tons of refined product.

NYE COUNTY

In our issue of last week the production of Tonopah for the first half of the current year was given as \$1,210,889. This should be \$6,210,889, as is apparent to those who are interested in this great camp.

There are 30 men employed at the Nevada Cinnabar Co.'s property at Ione. Material for the furnace and buildings is arriving at Austin by train, and is then carried up Reese river on a 5-ton Pierce-Arrow auto-truck. About 100,000 bricks have been made, while 400,000 are necessary. There is enough ore opened to keep the 50-ton furnace busy for about a year.

During the week ended July 12, the mines at Tonopah produced 9681 tons of ore worth \$224,375. The decrease was due to the holidays. In June, the Belmont mill produced 397,504 oz. of bullion from 15,214 tons, with a profit of \$182,971. The Halifax made its first shipment of 50 tons of ore to the West End mill for a bulk test. The mine is opening satisfactorily. On the 600-ft. level of the West End, rich sulphide ore was opened last week.

STOREY COUNTY

The monthly expenses of the United Comstock Pumping Association since December 1, 1912, have been as follows: \$19,719, \$20,393, \$18,058, \$16,233, \$15,278, and \$15,656. These include all salaries and wages, supplies, power, hoisting, air, and pump repairs. The rearrangement of pumps was an important job, and has been proved to be beneficial.

NEW MEXICO

EDDY COUNTY

Arrangements for drilling in the Carlsbad field are about completed. About 12 years ago some prospecting for oil was done here, and oil men now think the district worth further trial. At Artesia, the Dayton Petroleum Co. has reached the second oil-sand at 1800 ft., showing oil and gas.

The Layton Petroleum Co., after encountering considerable resistance from a hard formation, has its test well down about 950 ft. and has set its 10-in. casing with a dry hole. The 12-in. casing was set at 700 ft. This is the first test well drilled in the valley, and is controlled by E. L. Doheny, of Los Angeles.

The Pecos Valley Gas & Oil Co. is down 750 ft. on the Martin well and has set its 10-in. casing at 600 ft. It has closed a contract with L. W. Feemster for drilling a well on the Terry lease, which is southwest of the Brown well. The derrick and machinery are in place and work will be commenced at once. The Company continues operating the Brown well that is producing about 50 bbl. of oil per day. Drilling continues by the company on the Fowler lease.

GRANT COUNTY

A large quantity of water has been encountered on the 400-ft. level of the Emma copper mine at Flerro, and has risen to the 200-ft. level. Larger pumps are being installed. The Colorado Fuel & Iron Co. continues to ship a big tonnage of iron ore to its plant at Pueblo, Colorado. The assessed value of the Flerro property has been set at \$53,591 by the county commissioners, and this value has been accepted. The assessed value of the Chino Copper Co.'s property is \$3,093,925, and net product at \$1,000,000. The Company accepts the former value, but will contest the latter.

SOCORRO COUNTY

This county produced gold valued at \$525,629, and 1,126.429 fine ounces of silver, being 67 and 73% of the total state yield, respectively, in 1912, according to the United States Geological Survey.

OREGON

BAKER COUNTY

(Special Correspondence.)—The Sumpter dredge is working three shifts of 8 hours each, the only time lost being about once a week when the clean-up is made. The value of the nugget found recently at Susanville, Grant county, was \$1408.75. The district is fairly active in that this year the mines within 60 miles of Baker will produce approximately \$2,400,000 in gold, as compared with about

\$750,000 for the entire state of Oregon in 1912. Eastern Oregon, with the introduction of electric power and dredges, is 'moving.'

Sumpter, July 13.

UTAH

BEAVER COUNTY

The adit at the Montreal group will be extended under the ore deposits that have been exposed near the surface. A big exhaust fan will be installed and rails laid. When this work is completed, machine drills will be placed at the face of the tunnel and development work pushed. The owners believe that they have a good mining proposition in the southern part of the state and purpose to carry on development work extensively.

On July 8 the offices and warehouse of the Horn Silver Mining Co. were destroyed by fire. It is alleged that the damage was purposely done by unknown persons. This is a well known and profitable company.

JUAB COUNTY

The Chief Consolidated M. Co. has declared a dividend of 10c. per share, amounting to \$87,640. Ore is being produced at a rate of 60,000 tons per year, and the mine is the second largest producer at Tintic. The main shaft causes some delay, as it is too small down to the 1200-ft. level. The Mammoth Mining Co. paid a dividend of 15c. per share on July 19, amounting to \$20,000, the total to date being \$2,300,000.

SUMMIT COUNTY

During June, Park City mines shipped 6819 tons of ore, as follows: Silver King Coalition, 3126 tons; Daly West, 1295; Daly-Judge, 1643; Silver King Consolidated, 218; lessees, 191; Mines Operating Co., 64; American Flag company, 42; Ontario-Johnson lease, 32; and Grasselli Chemical Co., 76 tons.

TOOELE COUNTY

Four reverberatory lead furnaces are working at the International plant, and a fifth will be ready in about a month. The lead slag plant, recovering a further percentage of metals, is giving good results.

UTAH COUNTY

The Iron Blossom company at Provo has declared a dividend of 10c. per share, amounting to \$100,000, making a total of \$1,670,000. The 300-ft. level of the Colorado mine is opening a fair tonnage of ore.

WASHINGTON

STEVENS COUNTY

The vein in the Hecla mine, Chewelah, has a width of about 8 ft. in the face of the drift, carrying copper and silver ore assaying from \$23 to \$93 per ton. About 70 tons of high-grade ore has been extracted and piled on the dump ready for shipment as soon as the wagon-road, about 1½ miles in length, is completed and other preliminaries finished.

Joseph T. Pardee, of the U. S. Geological Survey, is completing his inspection of the Colville reservation. Work in 1912 showed that part of the area east of Nespelem, which contains most of the mineral deposits, has been classified. Although some of the lands classified as mineral have been proved by underground work to contain valuable orebodies, most of the lands have not been developed, and their mineral classification is based upon evidence offered by the surface and by the geology of the region in general.

WYOMING

UINTA COUNTY

Within about two months, the United States Phosphate Co., a Salt Lake organization, will have in operation its grinding plant at Border, the first company to install equipment within the phosphate deposits of Wyoming, Utah, and Idaho. This Company for over a year has been making regular shipments of the crude rock to the various markets around Salt Lake City, but the plant now being erected will grind 95% of the rock to 100 mesh, thereby bringing it into immediate shape for use as a fertilizer. The plant will have a capacity of 100 tons per day.

CANADA

ONTARIO

Bullion shipments from Cobalt during the week ended June 28 were 186,332 oz., valued at \$108,204. La Rose sent to the Deloro plant at Marmora 54 tons of ore containing 151,658 oz. silver. According to the Bureau of Mines of Ontario, the first quarter of the current year resulted in the following production:

Product.	Quantity.	Value.
Gold, ounces	50,637	\$1,030,920
Silver, ounces	7,264,559	4,040,450
Copper, tons	3,075	436,328
Nickel, tons	6,311	1,309,870
Iron ore, tons	15,389	25,695
Pig iron, tons	181,042	2,506,175
Cobalt and nickel oxides, pounds..	280,096	120,500

YUKON

The Mayo district is showing considerable activity. On Highet and Dublin creeks, 28 men are working. The roads are rough and ought to be improved to help the district.

COLOMBIA

A corps of engineers of the Breitung Mines Corporation arrived in Barranquilla in April last for the purpose of exploring mines in the republic. The party has mining tools and instruments, gasoline motor-boats, and other supplies, and is said to be the best equipped mining expedition that has ever come into the country with the object of making explorations on a large scale.

MEXICO

On April 11, 1913, the Government published a list of 100 mines declared void since October 24, 1912, according to the law of June 6, 1892. Similar lists have appeared earlier. These mines had been located, 24 in the state of Tamaulipas and 76 in the state of Zacatecas. Most of them were for both gold and silver, but many had been denounced as containing silver and lead, a few with copper, and several of either gold or silver alone. The largest was for a copper mine in Zacatecas of 50 hectares (123½ acres), the smallest for a mine of silver and gold in Zacatecas of only 0.37 hectare.

PHILIPPINE ISLANDS

Gold has been discovered on the banks of the Marquina river within 15 miles of Manila. The Malaguit Dredging Co. has been incorporated at ₱1,000,000 to take over from A. J. MacDonald 480 acres of placer claims on the Malaguit river. It is reported that the dredge now on the ground saves 200 oz. of gold per month from the placer workings. The incorporation of this company means that more dredges will be installed in the Camarines to work the claims, and good results are expected in the near future.

According to press reports, the Guamos Placer Co. has liquidated its debt of ₱38,000 since last November, and up to April 3 had paid ₱175,000 in dividends. The capital of the company is ₱500,000. It is figured that 10%, or ₱50,000, will be paid monthly. The Philippine Exploration Co. holds 55% of the Guamos stock. The past six months' output from the dredge was ₱\$328,000, which gives an idea of dredging possibilities on the Paracale river. Other dredges operating are those of the Maximelo Gold Dredging Co. and the Paracale Bucket Dredging Proprietary, Ltd. The latter is a Melbourne, Australia, concern. Its new 7-ft., close-connected dredge is nearly complete. Another Australian company, the Philippines Dredging Proprietary, Ltd., is building a dredge nearby. On the Malaguit river, a Risdon dredge, under J. A. Bruce, has been producing about 250 oz. of gold per month for some time. There is said to be 3000 acres of gold-bearing ground on this river, of which 1000 acres are suitable for dredging. A dredge with a steel hull is to be installed on the Umival river, which flows into Dingaban bay, on the east coast of Luzon. Sydney, New South Wales, people are providing the money. The Luzon Gold Co. has acquired ground in the upper reaches of the river. The

quartz properties in the Paracale district are attracting attention. The Surigao Gold Mining Co., at Surigao, will build a hydraulic plant of 100,000 cu. yd. monthly capacity during the next eight months. About 1000 acres of gravel are available, and it should average 29 centavos per cubic yard. Those chiefly interested in the company are D. M. Carman, E. O. Parker, George C. Sellner, Ralph McCulloch, and C. A. Briggs. Mr. Carman was in Manila recently.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

H. S. COE is leaving for Nicaragua.

J. PARKE CHANNING has been at Butte.

LIONEL E. HILL has returned to Rosslund, B. C., from London.

E. P. JENNINGS has returned from a professional visit to Tintic, Utah.

PAUL R. FANNING, metallurgist for the Division of Mines, at Manila, is at Grass Valley.

P. G. BECKETT, general manager for the Old Dominion Copper M. & S. Co. is on the Coast.

FRANK H. PROBERT is in the East, and is not expected to return to Los Angeles for six weeks.

ROBERT H. CHAPMAN will be for several months with the Geological Survey, Yerington, Nevada.

ALGERNON DEL MAR has resigned from the superintendency of the Bishop Creek Milling Company.

WILLIAM MALONEY, of Nome, has been appointed territorial mine inspector, with headquarters at Nome.

VICTOR C. ALDERSON was seriously injured recently in an accident near the drainage tunnel at Cripple Creek.

FRANCIS P. BRAY has visited Broken Hill Proprietary works at Port Pirie and Iron Mountain, South Australia.

FAYETTE A. JONES, of Albuquerque, was, on July 15, elected president of the New Mexico State School of Mines.

J. B. TYRRELL is making a short visit to the Hurricanaw district in northern Quebec to investigate some recent gold discoveries.

D. C. JACKLING, FRANK JANNEY, W. O. BRADLEY, and HARRY E. TOOKER are at Juneau, visiting the property of the Alaska Gold Mines.

JACK E. SHAW, recently assistant superintendent of the Gaston Gold Mining Co., is now superintendent of the Birchville Mining Co., at Graniteville, California.

JOSEPHUS DANIELS, Secretary of the Navy, will be the guest of the San Francisco Chamber of Commerce at a banquet to be held on July 25, at the St. Francis hotel.

WALTER J. RADFORD has accepted the position of engineer for the company operating the Lady Belle Lease at Eagle, Colorado, and will have his headquarters at Denver.

J. H. BATCHELLER has resigned his position as metallurgist for the Tomboy Gold Mines Co., Ltd., of Telluride, Colorado, and is temporarily on professional business at Tonopah.

GEORGE J. YOUNG, head of the Mackay School of Mines of the University of Nevada, has resigned to accept a position as professor of mining and metallurgy in the University of Minnesota.

B. A. BOSQUI will leave San Francisco shortly to take charge of the new mill of the Commonwealth Mining Co., at Pearce, Arizona. The plant will probably be ready for operation during August.

H. C. WILMOT has resigned as superintendent of the Colorado Mining Co., Arroyo, Masbate, Philippines. After having examined the property and designed the mill for the Syndicate Mining Co., he has accepted the managership.

The engagement is announced of Miss ELIZABETH MCNEAR, of Oakland, California, to JOHN POWER HUTCHINS, of St. Petersburg, Russia. The wedding will take place in October at the residence of Mr. and Mrs. Edgar Rickard in London.

EASTERN METAL MARKET
(By wire from New York.)

NEW YORK, July 17.—Copper has shown a slight change for the better, and the market is firmer. No large sales are reported. The visible supply afloat, on July 15, in England and France is stated to be 29,358 tons, which is a slight increase for the past two weeks. Rotterdam, Hamburg, and Bremen stocks show a decrease of 2109 tons. The lead market is quiet, and spelter remains dull with but little trading reported. The London market closed on July 16 with copper spot at £63 and futures £63 5s. Lead £20, and spelter £20 10s. Tin is quoted at £181 15s. and futures at £182 5s.

QUICKSILVER

The primary market for quicksilver is San Francisco, California, being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 7½ lb., are given below:

COPPER			
Quotations on copper as published in this column represent average wholesale transactions on the New York market and refer to electrolytic copper. Lake copper commands normally from 1-5 to 1-4c. per lb. more. Prices are in cents per pound.

PRESENT CONDITION OF COPPER MARKET

It is difficult to comment upon the New York copper-metal market, except as an example of how long it is possible for consumers to stay out of the market. For over a month there has been no extensive buying of copper, and the average metal prices quoted in this and other journals have been more or less in the nature of approximations, for there has been little or no buying at the prices named by the large agencies, while the amounts which have changed hands at prices "below the market" are not commonly important enough to establish quotations. It was expected that if the Copper Producers' Association figures on July 9 showed a decrease in the stocks, buying would be resumed. The figures were favorable, showing a decrease of nearly 15,000,000 lb. in the metal on hand at the end of June, as compared with the beginning of the month. The foreign stocks also showed a decrease of 5,000,000 lb., so that the world's visible supply on July 1 was 20,000,000 lb. less than on June 1, and nearly 10,000,000 lb. below the previous minimum record. Figures for the half-year in the United States are now available, showing that the output of the refineries was 809,194,006 lb., and total deliveries of 861,692,002 lb. The decrease in refinery output in June was largely due to the shut-down of the Nichols refinery, at Laurel Hill, though mine production (during April, it should be remembered) also shows a slackening. Cananea and Miami have been in difficulties about that time. Work at Laurel Hill has been resumed, but output will not reach normal at the plant for some time, as it requires some time to get a large refinery into its stride. All this has left consumers utterly unmoved, and the agencies then dropped their quotations ½c. per pound. This was also without any result, and on July 11 there were no sales of any importance recorded, though plenty of copper was available at 14½c., delivered 30 days. Exports for the first ten days of July were 7985 tons, as compared with 11,945 tons for the same period last year. Cables from London state that the Amalgamated agency had reduced the price of electrolytic to £67, the equivalent of 14½c., while the A. S. & R. is offering at £66 1s. and dealers are selling September copper at £66, corresponding to 14½c., and even at these prices the demand was poor. As a contrast to the dull state of the copper sellers is the booming business of the American Brass Co., one of the large consumers, which is said to be receiving orders faster than they can be attended to, and to be planning extensive additions to its plant. It is only a question of time, of course, until consumers will have reduced their stocks to the point where it will be necessary to come back to replenish them; meanwhile they are giving an interesting exhibition of the importance of the so-called invisible stocks of copper.

Movement of copper in Germany from January to May, 1913, were as follows: Imports, 94,920 tons; exports, 4353 tons; consumption, 90,567 tons; compared with 80,347 tons during the same period of 1912.

Copper Statistics and the Copper Market

*During 1912 the world's production of copper was 1,008,290 long tons, against 869,370 tons in 1911, as shown in the following table:

Producing countries.	1904.	1908.	1911.	1912.
United States	362,700	420,790	487,300	557,590

Totals	67,442	748,480	973,535	1,057,751
†Estimated.				

An absolute comparison between the figures of production and consumption is impossible, as the latter include the imports of manufactures of some countries, although these also appear in the consumption totals of the country of origin. The quantities of old metal, which are not shown statistically, also render an exact comparison impossible.

The outlook was rather obscured at the beginning of the present year. The war cloud in the Balkans had not lifted, and there was not that improvement in the strained economic situation which could ease the financial burden of European countries. There were also signs of a relapse in the United States, which first became apparent early in December, and were more marked as the time for the new President to take office approached, and uneasiness at the

*From 'Statistical Compilations About Copper,' issued by L. Vogelstein & Co., New York, representing Aron Hirsch & Sohn, Halberstadt, Germany.

certainly of tariff revision was increased by the uncertainty as to when these changes would come into effect. Moreover, the attitude of the new democratic President toward capital and trusts was viewed with trepidation. At the time of publication, in March, the international pendulum is swinging toward better conditions. The monetary stringency in Enrope has become less keen, and peace in the Balkans is at hand. In the copper-consuming industries fresh activity is promised, not alone by reason of increase in armaments, but also by works of peace, as the development of the territories acquired by the Balkan states, the building of power-stations, etc. Recent increases of capital of the German electrical companies foreshadow further extension. In America, generally, the internal situation is still regarded as excellent. Business here has not slackened, and after making due allowance for domestic political unrest, it must be admitted that the business situation in the United States since 1905 and 1906 has never been so healthy as at present. The view is now gaining ground that the tariff changes will not be of a very radical nature. Provided the harvest is at least up to the average, and the international money market not unduly burdened, the hope may reasonably be expressed that trade conditions in the United States in the second half of 1913 will be as good as, if not better than, at any time in 1912.

Even though producers will have to reckon with a lower price level than obtained in the last months of 1912, exaggerated fears of a decline in price are to be deprecated. The outlook for consumption promises well, and the copper-consuming industries may look ahead with confidence.

Stocks on hand at the end of the last four years is estimated as follows, in long tons:

	1909.	1910.	1911.	1912.
United States	63,289	54,480	39,937	47,016
England	95,673	66,917	42,104	27,763
France	6,299	6,080	5,254	4,396
Rotterdam and Hamburg	2,200	16,300	13,400	2,882
Totals	167,461	143,777	100,695	82,057

The average price of electrolytic and lake copper in New York since 1903 is as follows, in cents per pound:

Electrolytic. Lake.			Electrolytic. Lake.				
1903	13.63	13.45	1908	13.22	13.38
1904	13.09	13.12	1909	13.02	13.35
1905	15.82	15.89	1910	12.80	13.02
1906	19.39	19.66	1911	12.47	12.64
1907	20.10	20.65	1912	16.43	16.56

Sulphuric Acid Production

The sulphuric acid production of the United States in 1912 was as follows, in short tons: 50°B., 1,047,483, valued at \$5,378,411; 60°B., 451,172, valued at \$2,727,764; 66°B., 774,772, valued at \$9,360,630; and other grades, 66,166, valued at \$871,214, according to the United States Geological Survey.

Sulphuric acid is produced in several grades: (1) 50°B. acid, also known as chamber acid, containing an average of 50.76% SO₃, or 62.18% H₂SO₄; (2) 60°B. acid, containing an average of 63.41 SO₃, or 77.67% H₂SO₄; (3) 66°B. acid, known as oil of vitriol, containing approximately 76% SO₃, or approximately 93.19% H₂SO₄. Higher strengths of acid usually contain SO₃ dissolved in sulphuric acid, for example, pyrosulphuric acid and fuming or Nordhausen acid. Oleum is a grade which contains 30% of free SO₃, or a total of 87.14% of free and combined SO₃.

The production from copper and zinc smelters was as follows, reduced to 60°B. acid:

	Tons.	Value.
Copper smelters	321,156	\$1,985,704
Zinc smelters	295,917	2,255,237
Total	614,073	\$4,240,941

This is 27% of the United States production, and an increase of 175,773 tons compared with 1911.

Decisions Relating to Mining

Specially reported for the MINING AND SCIENTIFIC PRESS.

OIL PLACERS IN LOUISIANA

A locator on placer ground belonging to the United States, surveyed or unsurveyed, is the equitable owner of the mining ground, and the government holds the premises in trust for him to be delivered upon the payment specified; and he has sufficient interest to maintain a defense to an action of ejectment.

Producers' Oil Co. v. Hanzen (Louisiana) 61 Southern, 754. March 31, 1913.

ANNUAL LABOR—FORFEITURE FOR NON-PERFORMANCE DENIED
Where a stockholder in a mining company had been employed to look after and superintend mining properties of the company, and the company failed to perform annual labor on its claims, the said stockholder, occupying a fiduciary relation to the company, will not be allowed to relocate the claims in his own name and divest the company of title thereto, but such re-location will be held as insuring to the benefit of the company.

Co-operative Copper & Gold Mining Co. v. Law (Oregon) 132 Pacific, 521. May 27, 1913.

CONSTRUCTIVE POSSESSION OF MINERALS

In 1874 the owner of a certain tract conveyed the surface rights therein reserving the minerals. The grantee went into possession of the surface, and he and his grantees, including complainant, remained in possession ever since: no one having any separate actual possession of the minerals. Held, that the possession of the minerals accompanied the possession of the surface, and the complainant having acquired title to the minerals by adverse possession, was in the constructive possession thereof, so as to entitle him to sue to quiet title to the mineral rights.

Moore v. Empire Land Co. (Alabama) 61 Southern 940. April 23, 1913.

COAL LEASE—ROYALTY CLAUSE CONSTRUED

A coal lease provided that a minimum royalty should be paid each year, that if insufficient coal were mined during a given year to enable this minimum royalty to be paid from the proceeds, that the balance should be paid in cash, but might be credited on the royalty of a succeeding year when the coal mined should be more than sufficient to make the payments. Held, that the lease did not contemplate that royalties in excess of the minimum, derived from the mining operations of a given year, could be credited on payment of the minimum royalty of a succeeding year.

Vandalia Coal Co. v. Underwood (Indiana) 101 Northwestern 1047. May 28, 1913.

FIXTURES ON MINING CLAIMS

What constitutes and what does not constitute a fixture upon a mining claim is a question which usually has to be passed upon anew every time a case comes up, owing to the difficulty of formulating general rules to govern each specific instance. For example, an engine and pump bolted and spiked to a wooden frame bedded in the ground sufficiently to make it level, has been held to be a fixture¹; an electric hoist, bolted to a substructure of timber and cement together with the head-frame and engine house surrounding it, were considered fixtures²; electric motors bolted to a concrete foundation, a transformer affixed to a pole, and an electric pump used in unwatering a mine were treated as fixtures.³ The intent with which the articles in question were placed on the claim has much to do with it, but this intent will be inferred from the character of the articles, use for which they were intended, and manner in which they are placed upon the soil. Ore extracted from a shaft and stock piled on adjoining land for future treatment, is personal property of the lessee and not a fixture.⁴ It is common practice for the lessee to stipulate in a mining lease for the removal of machinery and buildings, placed or to be placed by him upon the claim, in the event of the subsequent forfeiture, abandonment, or termination of the

lease, and in such event he has a clear right to remove them. It would seem that a shaft-house and head-frame might be removed under such a clause if it could be done without permanent injury to the mine.
¹Merritt v. Tudd, 14 California, 59.
²Arnold v. Goldfield, etc., Mining Co., 109 Pacific, 718.
³Conde v. Sweeney, 116 Pacific, 319.
⁴Ritter v. Lynch, 123 Federal, 930.

Petroleum Production in United States

The great production of petroleum in 1911, which was 220,449,391 bbl., was equaled and passed in 1912, when the total reached 222,538,604 bbl. Higher prices were the rule in 1912 except in California, and even in that state there was no material decline. The total value, therefore, increased markedly, reaching \$164,087,342, or 22.41% above the value for 1911, according to the United States Geological Survey. The greatest increase in quantity was in California, where the total advanced from 81,134,391 to 86,450,767 bbl., a gain of 5,316,376 bbl., or 6.55%. Wyoming showed the remarkable gain of 742%, from 186,695 bbl. to 1,572,306 bbl., owing to the increased activity of the Mid-West Oil Co. and the Wyoming Oil Fields Co. Operations in northern Texas also more than offset the usual decline in the Gulf region and resulted in a significant gain for the state.

The volume of crude oil and of all the usual products exported from the United States increased, owing to the fact that foreign conditions were much more favorable to American exporters. Meanwhile the importation of gasoline from the East Indies was a favorable element in relieving the growing demand for this product on the Pacific coast. The improved conditions in the export trade and the increased capacity of the refiners to take care of the great yield of crude oil resulted in a marked decline in stocks in all fields except California, and even there the storage of petroleum was checked by an increase in consumption.

The total stocks of all crude oils at the beginning of 1912 aggregated 138,000,000 bbl. By the close of the year they had declined to 125,000,000 bbl., a decrease of about 10%. The decline was greatest in the fields east of the Rocky Mountains, where on January 1, 1912, the stocks aggregated 94,000,000 bbl.; they were reduced during the year to 79,000,000 bbl., a decrease of about 16 per cent.

This decline at once brought out a marked stimulation of prices all over the East, with a view to increasing the activity of drilling. Its effect was so marked that the natural decline of the older fields was checked. Even Ohio showed a slight increase in production in 1912 for the first time in 12 years.

The total production by states is given below:

State.	Production (barrels).	
	1911.	1912.
California	81,134,391	86,450,767
Colorado	226,926	206,052
Illinois	31,317,038	28,601,308
Indiana	1,695,289	970,009
Kansas	1,278,819	1,592,796
Kentucky	472,458	484,368
Louisiana	10,720,420	9,263,439
Michigan	7,995	*
Missouri		
New York	952,515	874,128
Ohio	8,817,112	8,969,007
Oklahoma	56,969,637	51,852,457
Pennsylvania	8,248,158	7,837,948
Texas	9,526,474	11,735,057
Utah	186,695	1,572,306
Wyoming		
West Virginia	9,795,464	12,128,962
Totals	220,449,391	222,538,604

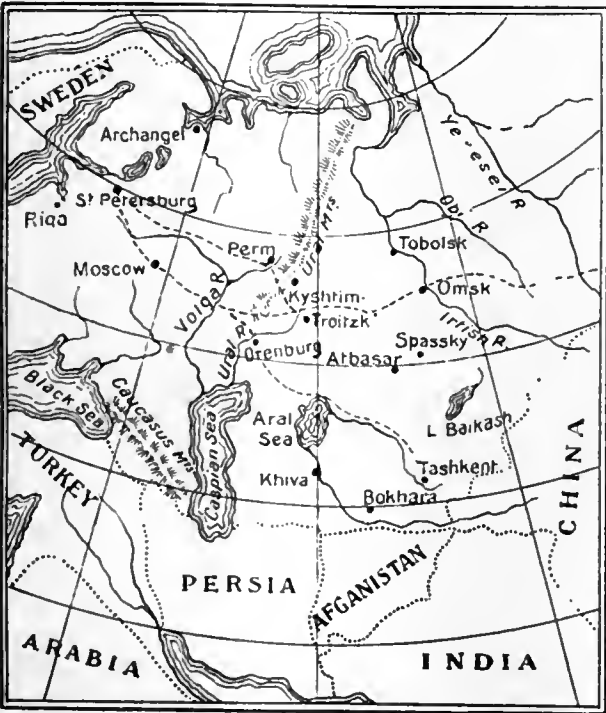

*Included in Ohio.

Prices ranged from 50.7c. per barrel in Wyoming to \$1.644 in Pennsylvania, while the average for all states was 73.7c., against 60.8c. per barrel in 1911.

Company Reports

SPASSKY COPPER MINE, LTD.

This Company was formed in 1904 to acquire the Yuspensky copper mine, the Spassky smelting works, and the Karagandy coal mine, in the Akmolinsk district of Siberia. In 1911 a controlling interest in the Atbasar company, owning another copper property to the southwest, was purchased. Last month the whole of the Atbasar property was absorbed by the Spassky company. The report of the Spassky for the year ended September 30 shows that 28,315 tons of ore was raised, averaging 20% copper. The smelter treated 23,759 tons, averaging 13.5% copper, yielding 3998 tons of metal. As regards development, the Annensky

-----RAILWAYS.BOUNDARIES.
RUSSIA AND WESTERN SIBERIA.

shaft has been sunk to 560 ft., and a level opened at that point with encouraging results. Further sinking is in progress. At the coal mine, 64,757 tons was raised, chiefly for use at the smelter. The income from the sale of copper was \$1,756,000, the average price being \$4368 per ton. The net profit was \$782,000, out of which \$719,000 has been paid as dividend, being at the rate of 25 per cent.

JUPITER GOLD MINING COMPANY, LTD.

This Company belongs to the Consolidated Gold Fields group, and was formed in 1896 to acquire property on the dip of what is now in the Geldenhuis Deep. As is known in mining circles, the Company owns a mill conjointly with the Simmer Deep, and the normal proportion of stamps is 120. Milling commenced in 1908, and the dividends so far paid have been 5% for 1909, and 5% for 1912. The capital is \$4,865,000. The report for 1912 shows that 492,789 tons of ore was mined, and, together with 21,391 tons from the dumps, sent to the sorting station, where 7.25% was removed as waste. The average number of stamps working was 100, and 6.3 tube-mills. The gold yield was worth \$2,342,000. Working costs were \$2,068,000. After sundry items of income and expenditure were included, the working profit was \$307,000. Out of this, \$245,000 was distributed as dividend, being at the rate of 5%. The working cost per ton was 75c. less than in 1911, and the yield per ton was 56c. less. The amount of ore treated was 161,800 tons greater, so the increased profit per ton and the increased tonnage contributed to an increased profit for the year of \$144,000. The scarcity of native labor has

led to more machine-drills being used, and during 1912 the proportion of ore broken by machines was 92%. The ore reserve on December 31 was estimated at 1,270,000 tons, averaging \$4.40 per ton, as compared with 1,232,511 tons, averaging \$5.10 the year before. The ore developed during the year was of poorer quality than the average, and the greater proportion of machine-drilling involving wider stopes accounts partly for the fall in average content of the reserve. It should be noted that the Jupiter and Simmer Deep companies now return their reserves in tons of ore in the mine, and not in milling tons allowing for the rejection of 10% waste. This alteration is due to the fact that the low grade of the ore makes it impossible to reject so large a proportion. The report refers to a proposed increase in the capacity of the mill from 45,000 to 60,000 tons per month, made possible by the recent improvement in the labor supply. The number of stamps will not be increased, but coarser crushing will be adopted, with extra tube-mills.

TEKKA, LIMITED

This Company belongs to the Wickett group, with headquarters in Redruth, Cornwall, England, and was formed in 1907 to acquire a property in the Kinta district of Perak, Federated Malay States, on the other side of the Kinta valley to the Tronoh and Lahat. In 1910 an additional property was purchased, in the Taiping district, north of Kinta. Dividends were first paid in 1909, and the profits have steadily grown. The Tekka ground is hydraulicked, and a suction-pump dredge is used at present at Taiping property. The report for the year ended January 31 last shows that at Tekka 593,493 cu. yd. was treated for a yield of 435 tons. The recovery was 1.64 lb. black tin per cubic yard. At Taiping, 296,356 cu. yd. was treated, yielding 127 tons, or 0.93 lb. per cubic yard. Development points to bucket-dredging as being the best method of working the deposit, and an alteration is contemplated. The total profit for the year was \$172,000, out of which \$144,000 has been distributed as dividend, being at the rate of 37.5%. Osborne & Chappel are the managers.

Gold Production of Western Australia

The gold production of Western Australia in April was \$2,195,300, the principal producers being as follows:

Name.	Tonnage.	Value.	Profit.	Dividend.
Great Boulder	18,212	\$240,000	\$127,800
Ivanhoe	19,715	188,400	70,000	\$275,000
Kalgoorli	10,620	107,000	46,200	120,000
Bullfinch	4,343	66,100	44,100
Fenian	2,750	53,900	33,400
Yuanmi	10,400	89,400	32,800
Golden Horse-Shoe ...	25,460	184,800	24,900
Victorious	8,550	56,800	20,000
Lake View & Star	18,226	105,500	18,600	50,000
Sons of Gwalla	13,400	105,400	14,500
Queen of the Hills ...	3,254	28,600	10,900
Sand Queen	1,230	23,700	10,000	7,500
Mararoa	2,630	24,100	9,100
Oroya Links	11,350	60,000	7,900
Mountain Queen	3,302	24,600	6,500
Perseverance	20,622	116,700	6,500	174,930
South Kalgoorli	9,694	55,000	6,500
Associated Northern...	1,940	30,000	7,000	87,500
Golden Ridge	2,894	22,300	5,000
Associated	10,435	56,400	4,200
Kyarra	895	14,000	3,800
Ingliston Consols	2,120	15,800	2,700
Lake View Consols	8,675	8,100	2,400
Menzies Consols	1,904	16,500	1,200
Burbanks Main Lode ..	2,052	22,500	100
			Loss.	
Great Fingall	5,896	55,000	830
Commodore	1,100	4,200	300

The production in general has shown a slight decline for the past year, but with the new producers which are being developed, the future outlook is bright.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

THE FOREST AREA of Canada covers about 800,000,000 acres.

COPPER PRODUCTION of the world in 1800 was 10,000 tons, while in 1912 it was 1,008,290.

PRODUCTIVE oil and gas wells in the United States in 1912 were 12,512 and 1811, respectively.

POWER CONSUMPTION of a 16 by 22-ft. Trent agitator at the Ohpir mill, Virginia City, Nevada, averages $4\frac{1}{2}$ horse-power.

'ROCK' STAMPED by the mills of the Lake Superior copper region amounted to 11,411,941 tons in 1912. Of this, 81.2% was amygdaloid, and 18.8% conglomerate 'rock.'

DUTY on impure sodium and potassium cyanide imported into Bolivia is \$1.412 per 100 lb. In addition to the regular customs duties, there is a surtax of 15% of the duties.

THE SLIME AND SAND from the concentrator at Anaconda is being made into tile and bricks at the Washoe brick plant. The product is experimental so far, but gives promise of success.

SILVER PRODUCTION of Michigan copper mines in 1912 was worth \$324,999. This is from the Keweenaw district, where both metals occur native in lodes remarkable for their extent and uniformity.

GOLD STEALING on the Rand and the disposal of the same in England has, it is reported, taken on a new form, in that the gold is exported in the form of process blocks. These look much like heavy 'electros.'

MINING CLAIMS granted in Peru during the fortnight ended June 1 were as follows: silver, 2; silver and copper, 12; coal, 3; and lead and silver, 1. These were situated in 13 different provinces, and were granted to 12 petitioners.

ANALYSES OF PYRRHOTITE show the following composition: from Sudbury, Canada, iron 56.39%, sulphur 38.91%, and nickel 4.66%; from Lancaster Gap, Pennsylvania, iron 55.82%, sulphur 38.59%, and nickel 5.99%; and from Mountain, Wisconsin, iron 56.154%, sulphur, 43.846%, and no nickel.

ELECTRIC POWER in Madrid, Spain, was recently reduced from 18 to 3c. per kilowatt-hour as the result of a rate war, but an agreement is being arranged to charge 7c. per kilowatt-hour. The Compañía Coöperativa Eléctrica Madrid derives its power from a hydro-electric plant 150 miles from Madrid.

SULPHUR PRODUCTION in the United States in 1912 was 303,472 long tons, valued at \$5,256,422, compared with 265,664 long tons, valued at \$4,787,049, in 1911, according to the United States Geological Survey. The sulphur came from Louisiana, Nevada, and Wyoming, the production of Louisiana being the dominant factor in the domestic sulphur industry.

EXTENSIONS of the Mt. Morgan, Queensland, ore deposits have never been found beyond the boundary of the holdings of the Mt. Morgan company. The Extension company has sunk a shaft 1992 ft., and a drill-hole was driven 3068 ft., besides other drilling and driving. Only traces of gold and copper were found. The company intends to persevere. Mt. Morgan has produced gold and copper worth \$86,000,000.

ANALYSIS of mine operations in the Transvaal during April, according to the Chamber of Mines, shows the following: Ore hoisted, 2,627,989 tons; percentage of waste

sorted, 11.78; ore milled, 2,356,204 tons; stamps working, 10,046; tube-mills working, 285; plants in operation 27.19 days of 24 hours each; stamp-duty, 8.85 tons per day; gold production, \$16,010,000, of which \$1,070,000 was from amalgamation and \$5,840,000 from cyanidation; and working costs of 60 companies averaged \$4.32 per ton.

ANEROID BAROMETER READINGS should always be made while the instrument lies flat. A good instrument is now made for mining purposes, so graduated that observations below sea-level may be taken. It has its entire circle graduated to represent 6 in. of the mercurial column between 27 and 33. The range of altitude extends between 2000 ft. below and 4000 ft. above sea-level. The altitude scale is divided into 10-ft. spaces, and may be read by verniers to single feet. The reading lens rotates about the circumference to facilitate such observation.

ELECTRIC TRACTION will be used on the new route from Spiez by way of the Loetschberg tunnel to Domodossola, Italy, the electric locomotives being constructed by the Oerlikon Machine Works, near Zurich, Switzerland. The weight of the locomotives is 112 tons, and they are fitted with two motors of 3000 hp., weighing 27 tons each. The cost of construction is about \$40,500, or twice that of an ordinary steam-engine. The overhead or trolley system is employed, a current of 15,000 volts being carried. The locomotives are capable of pulling a train weighing 310 tons up the maximum grades of 27 per 1000 at the rate of 31 miles per hour.

BAUXITE is the principal ore of aluminum and is mined largely in Arkansas. It is a result of weathering of crystalline rocks. In part it has been redeposited in Cretaceous clays. It probably occurs at a number of places where it has been overlooked, as it may easily be confused with low-grade iron ore, or even iron-stained clay. It is really a hydroxide of alumina and contains 34 to 45% aluminum when pure. It is whitish, yellowish, or brownish in color; dull and earthy as to lustre; has no crystal form and no cleavage; breaks with a smooth to uneven fracture; has a white to pale yellowish streak; is 1 to 3 in hardness; and has a specific gravity of 2.5. It is most frequently oolitic or pisolitic in form, and that is the most ready means of recognizing it in the field. However, it also occurs in granular earthy form which is deceiving. It yields water at high temperatures in a closed tube, is difficult to dissolve in hydrochloric acid, and is infusible, but gives a deep blue test with cobalt nitrate. The United States production in recent years has been about 150,000 tons per year, and the average price at the mine about \$5 per long ton. Being a surface material, it is usually cheaply mined.

ORE DEPOSITS of the Joplin district, Missouri, vary in character with the depth of mining. The shallower ores beginning at the surface are universally pockety and are found in residual clays or in 'runs' in the basal breccias of the region. The breccias and the forms of the 'runs' are largely, if not altogether, due to solution of the limestone strata. One form of run, according to B. S. Butler and J. P. Dunlop, of the United States Geological Survey, which is fairly numerous, is the 'circle' deposit, which, in the popular view, has come to be nearly synonymous with rich deposits. Small veins, vertical sheets, and thin crevice deposits are often found in prospecting, but unless they develop into stringers leading into paying orebodies, are forgotten in the multitude of rich pockety deposits which the district has yielded. The blanket deposits or 'sheet ground' are found in the Grand Falls chert member of the Boone limestone, at depths varying from 125 to 275 ft., depending on the topography and the geologic structure. Below this horizon there are, in the rocks of Kinderhook age, deposits of disseminated ore. They have been found in prospect shafts or drill-holes near Springfield, Aurora, Granby, Cartersville, Joplin, Hornet, and Cave Springs, in Missouri; at Galena, in Kansas; and at Quapaw, in Oklahoma.

Copper Leaching at the Nevada-Douglas Property

Leaching processes are having their inning in the copper world at present. In addition to those recently reported, the Nevada-Douglas Copper Co.'s principals claim to have been successful in conducting experiments for some months under the supervision of W. L. Austin, bringing the process to a point where it can be operated commercially to produce copper at a cost of 7 to 10c. per pound. Laboratory results show costs at Butte with a similar process to be 5c. per pound. The Nevada-Douglas management is jubilant over the success of these experiments on both the high and low-grade ores of the mines. The ore is pulverized and leached with 10% sulphuric acid, and it is claimed tests have shown that agitation for two hours will give an extraction of 85%. After the copper is dissolved it is precipitated from the solution by an electrolytic process, the same as that employed in the Atlantic coast refineries. That there is a good future for the leaching process as applied to copper ores seems evident, and the mining public will await with interest the results when tried on a working scale. J. Parke Channing is of the opinion that leaching methods will prove most effective in saving the copper now lost in treating the ores of Miami.

Commercial Paragraphs

The **HARDINGE CONICAL MILL CO.**, believing that it will be conferring a benefit upon the users of cylindrical tube-mills without material injury to its own interests, begs to inform such users of cylindrical tube-mills that it will grant a limited number of privileges for converting cylindrical tube-mills into Hardinge mills upon the following conditions: 1st. That the owner or user of a tube-mill will furnish the Hardinge Conical Mill Co. with dimensions of the unconverted tube-mill, also information relative to the work now being done and which will be required of the mill after conversion, but the privilege shall only apply to tube-mills installed previous to January 1, 1913. 2nd. That the converted tube-mill shall bear a license plate which will be furnished by the Hardinge Conical Mill Co. 3rd. The consideration for the privilege shall be \$1 upon the furnishing of the license plate, and the further consideration of information relative to the comparative merits of the mill before and after conversion, as soon as such information is available. 4th. The granting of such privilege shall be entirely at the discretion of the Hardinge Conical Mill Co. and is at present intended only for applications received during the remainder of the year 1913. 5th. The unlicensed use of any such converted tube-mill, without the written authority of the Hardinge Conical Mill Co., will be construed and prosecuted as an infringement of its patents, which have already been adjudicated in favor of the Hardinge Conical Mill Co. in the United States Circuit Court and the United States Circuit Court of Appeals.

THE GOLDFIELDS WATER SCHEME, which supplies the Eastern Goldfields and many farming districts in Western Australia, showed a consumption of 1,134,800,000 gal. during the year that ended on June 30, 1912. Of this, the mines used 449,400,000, and mining towns 307,500,000 gal., a total of 756,900,000 gal. The revenue from all sources was \$1,100,000, operating expenses, including pumping, maintenance, management, etc., \$375,000, interest \$499,000, and sinking fund \$455,000, leaving a deficit of \$129,000. Pipes cover a length of 1016 miles.

The Eureka T & T Hook

This contrivance was invented for use in the tie preserving plants of Montana. The special features of the hook consist of the two points on the hook and two opposing spurs on the toe ring, giving a non-swiveling grip on the timber, box, or barrel to which it is fastened. With this hook a corner hold from right or left and an end-lifting hold for carrying and piling can be had, using two opposite hooks. It can also be used as a lug-hook for pole work. It will be found of especial value in handling short

THE EUREKA HOOK.

timber about the framing shed, in the preserving plant, at the shaft or slope, and on the underground stations. It can be used to advantage in handling boxes of castings, hardware, etc., and in all kinds of railroad work. The verdict of the tie and lumber men and the miners of this state is expressed in the question repeatedly asked when shown the tool, "It is so simple, why has someone not thought of it before?" The hook has been well received by the miners as well as the lumbermen. The tool shown in the illustration is 18 in. long and adapted to standard ties. Two larger sizes are contemplated for mine timber and use on carriages in the sawmills where such a hook is required. The hook was patented on June 24, 1913, and is manufactured by the Eureka Tie & Timber Hook Co., of Helena, Montana. The hook is a valuable asset in mining and railway construction work.

The 'Neptune' Diving Apparatus

This apparatus is designed particularly for work in flooded mines and other difficult situations where the use of air-pumps and tubes would be impracticable. The wearer is supplied with a perfectly respirable air without the aid of air-pumps, tubes, or any communication whatever with the surface. The maximum depth of water at which the apparatus can be safely used is 60 ft., and the duration of supply one hour with one cylinder, or two hours with two cylinders. The principle of the apparatus is that the wearer breathes the same air several times over, the carbonic acid being absorbed from the exhaled breath, and the requisite amount of oxygen restored to it, thus rendering it pure and fit for inhalation again. The apparatus consists of a patent diving helmet and dress in combination with a steel cylinder or cylinders containing compressed oxygen and atmospheric air in certain proportions, and a metal chamber containing a substance which absorbs the carbonic acid of the exhaled air. It is fitted with valves which allow the air and oxygen to pass into the helmet and dress in the required quantity, no matter at what depth the diver may be working. There is also a patented safety device whereby, in the event of a valve failing, the diver would be enabled to supply the requisite amount of air independently of the valves. Any excess of air that accumulates in the dress escapes automatically.

The apparatus is manufactured by Siebe, Gorman & Co., Ltd., London, S.E. The American representative is H. N. Elmer, 1140 Monadnock block, Chicago, Illinois.

Sears' Acme Mill

The 'Acme' mill was evolved from experience, which showed the possibilities of, and the actual need for, in the mining field, an improved mill of the Chilean principle, adapted to the practical and efficient fine grinding of ores, for amalgamation, concentration, or cyanidation.

This mill is especially adapted to the work of amalgamation, is versatile, convenient to operate or repair, automatic in adjustment for wear, has automatic feed, and is continuous in operation. In short, a mill with capacity, effectiveness, and none of the objectionable features of former mills.

It is not an experiment, for the principle is older than the stamp-mill, and has been thoroughly tested. It differs from other mills of this style vastly in the improved mechanical design, to better adapt it for amalgamation, facilitate the general operation, and eliminate the causes of vexatious delays and annoyances, so numerous in other designs. It is claimed that there is no other mill made which can be cleaned so quickly or thoroughly. By a convenient arrangement the spider and wheels are removed at one lift, then the die is taken out, and the mill may be cleaned easily and thoroughly. The whole operation of taking out spider and die, cleaning mill, and replacing working parts ready for new run can be accomplished in less than one hour. This feature is especially valuable in a custom mill. There are no adjustments necessary but that can be made while the mill is in operation, such as adjusting to change from a low-grade to a high-grade ore, or vice versa, or from maximum to minimum capacity, changing or renewing screens, or raising or lowering discharge. It can therefore run for 60 days without a moment's stop.

The arrangement for starting up with a load in the mill is an original and exclusive feature. In other makes of Chilean mills, if they have to be stopped with a load in them, it is necessary to shovel it out before starting, or run the risk of breaking the gearing or some other part of the machinery, whereas with this mill there is absolutely no danger, as it can be stopped at any time, and started with ease and safety with maximum load. No grease can get in from any of the bearings and they can be lubricated just as needed, at all times, while running.

The amalgamating features are the best that can be designed from years of experience.

Entirely automatic adjustment to compensate for wear on tires and die; and automatic feed, are two strong points. Variable capacity by changing speed and raising or lowering discharge while running, is another important feature. The screens have long life, owing to their proper position above die; are reversible and changeable, and in plain sight of the operator at all times. Friction is reduced to the minimum by roller and ball bearings, saving horsepower, wear, and lubricant. The cost of upkeep has been reduced to the minimum.

It is designed and built by an experienced millman, who knows from the millman's standpoint, what is necessary in a mill of this kind to make it practical, effective, convenient, and durable. This mill has a capacity of 20 to 60 tons per 24 hours, according to the material and size to which reduced. Feed must be $\frac{1}{4}$ -in. mesh to get the above capacities, but as coarse as $\frac{1}{2}$ to $\frac{3}{4}$ -in. feed may be used. Five to ten horse-power will be required, varying according to speed. Fifteen to thirty revolutions should be the limit within which the best results can be secured.

One or more of these mills installed below stamps, or any other auxiliary crushers reducing to $\frac{1}{4}$ -in. mesh, will increase tonnage, and at the same time increase saving by amalgamation, putting the pulp in the best condition for concentration or cyanidation, and in many cases eliminate the necessity for cyaniding by the increased extraction due to finer grinding. The mill is manufactured by the Sears-Smith Engineering Co., of Stockton, California.

EDITORIAL

ONCE more the spot-light has been turned on the high-cost-of-living question. Surely it would seem that the times are out of joint when a cabinet officer is forced, by his own statement, to carry a side line of lectures in order to make both ends meet. However, with a stipend of \$12,000 a year and a grape-juice diet it is a question, under the present delicate diplomatic situation, whether it would not be more expedient to devote a greater time to decreasing expenditure and less to increasing income.

IT is extremely gratifying to note that the Government is to establish a metallurgical and testing plant at Salt Lake City, which will be ready for operation about October 1. It will not be the purpose of this station to supplant private enterprises, but to conduct research work in the treatment of refractory ores and low-grade deposits which are at present beyond the pale of profitable investments. The motive is solely for conservation, and it is to be hoped that the large tonnage of lead-zinc ores which are in the mines and on the dumps throughout the Middle West may be turned into good investments through the efforts of this branch of the Bureau of Mines.

REACHING its majority was recently signalized by the Institution of Mining and Metallurgy of London by the raising of a twenty-first anniversary fund to serve as a permanent endowment for the society. To this, as a memorial to the late Sir Julius Wernher, his widow has subscribed £10,000, and others have contributed smaller sums. Recently a freehold house at the corner of Finsbury Circus and West street, and but a few yards from the centre of mining activities in London, was purchased for £9500, and, after being redecorated, will serve as the headquarters of the Institution's activities. The cost of this is practically already met by those subscriptions which are available for expenditure in this form, and it is confidently expected that the small temporary deficit will be promptly met by further subscriptions. What the Institution has been able to accomplish during the twenty-one years of its existence speaks for itself; we need not gild the lily. But we desire to compliment it upon the modesty of its present plans. When the American Institute of Mining Engineers acquired its permanent home, expenditure was upon so lavish a scale that the pressure of the 'high cost of living' was felt for years afterward, and the land debt has only just been liquidated, through the untiring efforts of Dr. James Douglas. Even allowing for

fundamental cost differences between New York and London, the expenditure of approximately \$55,000 to secure a permanent home for the Institution is commendably modest indeed. London is the great centre of world activities, and the engineer who comes from the far corners of the earth can now find within a few steps of Salisbury House and London Wall all those social, professional, and technical relationships and activities that he has missed in his period of exile.

Prices and Quotations

Not a few anomalies are presented in the prices at which various commodities are sold. A man's hat costs practically the same, no matter what the time of the year, or where it is bought; a bushel of wheat sells for one price today, another tomorrow, and at different prices today according to the place and time of delivery. Yet wheat is scarcely more likely to decrease in value if its sale be delayed than is a hat, and its transportation certainly offers no more difficulty, nor represents a larger proportion of its value than is the case with a hat. The reason for this curious contrast is that wheat is a commodity in which there is active speculation, based upon varying but imperative demand, while in the case of hats and similar commodities there is no such speculation. If an operator were to corner felt hats, the public would promptly take to wearing straw head-coverings; but if manipulators corner No. 1 hard wheat, millers cannot expect to be able to feed the public with graham flour or cornmeal. Under which of these two forms of selling the public reaps the greatest advantage is at least open to question. Evidently the stable selling price suits the producer best, for the first action of a concern which obtains control of the production of any commodity is to place selling upon a fixed-price basis. Where competition is restricted, the producer alternates between large gains and heavy losses.

As a whole, metals sell in this country on a competitive basis, though not upon a basis for speculation, generally speaking. In this our chief metal market, New York, differs in marked degree from London, where there is active speculation in metals. In the case of copper, for example, the chief producers sell directly to the principal consumers, either directly or through affiliated agencies, and nothing is sold except the actual metal. In London, on the contrary, there is a large business in copper warrants, which do not differ materially in character from the cotton futures which it has recently been proposed to tax out of existence. Why this is not done in New York is perhaps largely due to the reason assigned by the Chinese farmer, who on being asked why the Chinese house is not provided with a north door to let in the breeze in summer, replied, "We do not have north doors to our houses." It is also due to the fact that the American consumer of copper apparently does not feel the need of 'hedging' his investments in the metal. The English consumer who buys a consignment of copper proceeds to sell, at the same time, a warrant upon the exchange for approximately the same amount. If the price of copper goes down

or up, the loss on the metal will be practically compensated by the gain on the warrant, or conversely.

Dealing in copper futures is therefore employed as a form of industrial insurance which may be utilized by the consumer of copper; it may be, and is, of course, also made a medium of unadulterated speculation by market operators. If the arguments of that group of individuals, who are strenuously upholding the necessity for continuing speculation in cotton futures, are valid, it would apparently be to the advantage of copper producers to have similar dealings in copper in the New York market, but business here has so far failed to evidence any necessity for it. A fundamental difference between the two commodities must not be overlooked; copper is continuously produced, while cotton all becomes available at picking time and must be fed slowly to the consumer throughout the ensuing year. Any lack of correspondence with the supply of copper and the demand is due to conditions other than seasonal changes. For years consumption has been leading the market; in other words, it has been so steady and of such large amount that it has governed the amount produced. When it tends to exceed production, the price of the metal tends to advance, properties become workable that at lower metal prices yield no profit, and the output increases. If it increases too fast, the price of copper falls, and the mines which are working on a narrow margin are obliged to shut down.

This simple relation is complicated by the lack of relation between the discovery of large valuable orebodies or the new methods of mining and metallurgy on the one hand, and on the other the rapid changes in the business world which may follow as a result of wars or business crises. Underlying these fundamental conditions is a maze of relationships that cause prices to fluctuate from day to day. If copper sells at 15 cents for any considerable period, it is only because producers are able to sell it at that figure and still make a fair operating profit. At all times they are willing to take more, if they can get it; at times they may be willing to sell for less, but year by year there exists what may be called a normal selling price for copper. Unfortunately this defies exact determination, for the metal may sell for 20 cents or 12 cents, when its norm is 16. For this reason it is impossible to determine the normal price by averaging actual prices over a long period, for the laws of chance do not strictly apply.

Another reason why this is impossible is that price quotations are at best but approximations. On any given day numerous agents are selling lots of copper of different sizes at prices which vary slightly. The average price realized may easily be approximated, but to determine it with precision would require exact information as to the weight and price of every lot of the metal sold, and the making of allowances for the difference in selling terms, if any exist. Furthermore, no real basis for quotations may exist. During June, in New York, copper declined from approximately 15½ cents per pound at the beginning of the month to 14½ cents at the close. But as a matter of fact, no considerable amounts of copper were sold at these or any

other figures. Finally, about the middle of July, buying was resumed in considerable volume on the basis of $14\frac{1}{4}$ to $14\frac{3}{8}$ cents. By averaging quotations, those days on which no copper was sold have equal weight with the days on which it was sold in large quantities. It is evident, therefore, that statistics regarding prices can never be brought upon a basis of absolute precision. The present method of computation of approximate averages offers, however, a useful guide to the trend of the market and furnishes a practicable basis upon which business transactions can be concluded.

Mining Schools and Politics

Politics has all too frequently paralyzed technical schools, and we regret keenly to chronicle the fact that two state mining schools have just suffered a shake-up, due fundamentally to partisan politics. Eleven years ago Mr. Regis Chauvenet, despite his learning and high standing in metallurgy, fell a victim to dissension within and politics without, and was retired from the presidency of the Colorado State School of Mines. This year his successor, Mr. Victor C. Alderson, has suffered the same fate. Despite the excellent situation and many favoring conditions, the school at Golden has failed somewhat to realize its opportunities and ambitions. It has sent out excellent engineers, and a number of mediocre ones; in which it is neither better nor worse than other mining schools. The question inevitably arises whether the graduates of which the school has reason to be proud, would not have been even better men if they had been trained by a more united faculty. Knowing something of the internal politics that seems inherent in the faculty of an educational institution, in the United States at least, we are frank to say that in our judgment the Colorado School of Mines has chronically suffered from more than the usual amount of this trouble. More than once professors have been forced out of the faculty. Matters would probably have gone smoother if there had been an even more complete change of personnel. Trouble within a faculty is bad enough, but interference for political purposes is worse, and we are told that the present Governor of Colorado protested that, this being a Democratic administration, there were too many Republican instructors at Golden! Since when, may we ask, has skill in technical work or in instruction been dependent upon a professor's belief as to the tariff? It is a disgrace to the United States that such matters should enter into the making of appointments in an educational institution, and any school that submits to such treatment is sure to lose standing. It is not a matter of personalities in the least. Whether Mr. Alderson or another administers the school is a minor matter as compared with the big question whether a harmonious faculty is to receive help from outside or to be torn by dissension and hindered by the overruling politicians. Mr. Alderson devoted his talents, and with excellent results, to building up the plant and increasing the funds of the school. We called attention some months since to the large testing laboratory that had been erected, in the

main as the result of his energy and persistence. The plant stands nearly idle because the funds to make it useful have been refused. This illustrates excellently the inevitable result of a changing policy dictated, not by the needs and purposes of the school, but by the assumed necessities of distribution of state funds to meet local political demands. The whole situation is a sorry one, and may well make engineers question whether it would not be wise to have fewer but better schools. Mr. William G. Haldane, who goes in as acting president, has our sympathy. He is young, capable, and energetic, but he comes from a divided faculty to a difficult position. Appointment of Mr. Chauvenet as President Emeritus is, we presume, an empty honor; one that even Mr. Chauvenet's friends may well regret. It is always a doubtful expedient to try and turn back the hands on the clock, and the appointment suggests an unwelcome complicity in intrigue that comports but poorly with his high standing among engineers. We hope this honor has come to him unsought, but we fear that his name is being used by those who have ulterior purposes.

The other school that is in difficulties is the Missouri School of Mines, which, while an organic part of the State University, maintains a separate staff and plant at Rolla. Always small, it has done good work and some of the leaders of the profession look back with gratitude to life within its doors. Mr. D. C. Jackling may be mentioned as one. This school was long the football of local partisan politics, and the president, Mr. L. E. Young, has resigned as a protest against the apparent purpose of the present Governor, Mr. Elliott W. Major, to thrust it back in the mire from which it has been climbing. The particular incident is minor, the difficulty arising over the award of the position of architect for a new building to Mr. H. H. Hohenschild. Mr. Hohenschild represents the county in the state senate and is the local Democratic 'boss.' He is no better or worse than many other political bosses. His calibre is perhaps sufficiently indicated by the fact that he regards the School of Mines as a local establishment, one of the counters in the political game, rather than an educational institution belonging to the state at large. Such a concept is medieval. We know that it does not accord with the best thought of Missouri, but the incident lends color to the gibes that are constantly thrown at citizens of the great middle state.

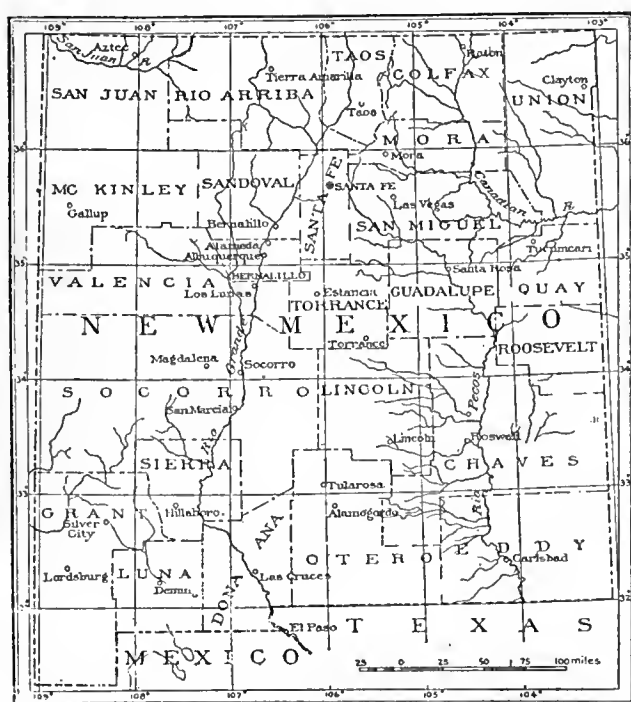

Such situations as are here discussed are perhaps inevitable incidents to evolution of popular government. That they represent but temporary stages in that evolution is evidenced by the independent position of the educational institutions of most of the states. They can not last long. We have much faith in the ultimate good sense and high purposes of the people of Colorado and Missouri, but it is an unwelcome revelation that civilization is so shallow in these states, which rank so high in mining. On behalf of mining men in and out of these states, we protest. It is no disgrace that a state school be small: its buildings may be inadequate, and its faculty need not necessarily be large; but the school must be free or it is a failure.

Sandstone Copper Deposits at Bent, New Mexico

By SYDNEY H. BALL

A brief examination of the property of the Tularosa Copper Co., made some time ago, resulted in certain conclusions regarding the origin of bedded copper deposits in sandstone, which perhaps are sufficient to justify the publication of the following notes. E. T. Kern, president of the Company, has kindly permitted their publication. An interesting account of this deposit has been recently published by L. C. Graton.¹ The conclusions arrived at by Mr. Graton and myself are, however, somewhat at variance.

W. Lindgren,² in a general article upon orebodies

MAP OF NEW MEXICO.

in sandstone, states that the characteristic metals are copper, lead, vanadium, and uranium, and that while ores of several metals sometimes occur together, "they are more commonly segregated into separate deposits in which one predominates." He recognizes as primary ores, chalcocite, bornite, chalcopyrite, pyrite, galena, roseocite, and earnotite. Gangues are inconspicuous, consisting of a little calcite, barite, and gypsum, the last probably of secondary origin. A little silver is usually present. Oxidized ores develop from the original ores. "The deposits are rather conspicuously confined to certain formations within the Permian, Jurassic, or Triassic. * * * More rarely the ores appear in fissures in the same formation * * * ." He mentions that the sedimentary rocks are either shallow marine or continental deposits. It has been my experience that such ores, when occurring in 'red beds', are usually confined to the gray or white interstratified members,

and do not occur in the highly ferric stained strata. As to their origin, Mr. Lindgren states: "In their present form the ores are assuredly epigenetic, but the evidence equally points to their having been concentrated by atmospheric waters from small quantities of metals disseminated in the rocks. It is believed, though the evidence of this is less direct, that the metals were carried down as sediments and solutions from older ore deposits in the adjacent continental areas." At the Tularosa mine, however, I believe that similar deposits have a dual origin, in part being derived directly or indirectly from the erosion of copper-bearing sediments, and in part being deposited through replacement by magmatic waters. As well known examples of deposits of this type may be mentioned the copper mines west of the Ural Mountains in the Government of Perm, Russia, once important producers, but now practically abandoned; the Atbasar copper mines on the Kirghese Steppes, Siberia; the Coro Coro mines in Bolivia, and numerous deposits in the 'red beds' of New Mexico, Arizona, and Colorado.

Tularosa Copper Company

The property of the Tularosa Copper Co. is situated at Bent, Otero county, New Mexico, on the Tularosa river. Bent is twelve miles northeast of Tularosa, a station on the El Paso & Southwestern railroad, lying about one hundred miles north-northeast of El Paso, Texas. The Company owns 307 acres of patented land, and in addition 670 acres on which sufficient work to patent has been performed. The property lies in the foothills of the Sierra Blanca range, which rises steeply to the east. Bent post office (elevation about 5570 ft.) is situated in a wide flat from which low broadly rounded ridges rise to the east, south, and north; to the west are steep hills 400 ft. high, succeeded farther on by an intricately dissected mesa sloping gently to a broad desert valley. The climate is delightful; timber is available within 6 miles, and the Tularosa river flows about 660 cu. ft. of water per minute. Unskilled Mexican labor is at hand, but miners must be brought in, for although scattered copper deposits occur for some 6 miles to the west, 12 miles to the north, and considerable distances to the east and south of Bent, no other mines were being worked in the district at the time of my visit.

The original location was made in 1870 by Andrew Wilson, upon a chalcocite-barite seam exposed in an arroyo, and shortly afterward a small furnace was erected. In December 1904, George Bent obtained an option on the property and in the following March the Tularosa Mining & Milling Co. was formed, which a couple of years later was reorganized as the Tularosa Copper Co. The 100-ton mill has recently resumed operations. The gross production to date has been about \$52,000: some \$11,000 was produced prior to 1905, and some \$40,000 by the Company largely from 1905 to 1907. The amount of develop-

¹'The Ore Deposits of New Mexico,' by Waldemar Lindgren, Louis C. Graton, and Charles H. Gordon, Prof. Paper 68, U. S. Geological Survey, pp. 187-190.

²*Economic Geology*, Vol. VI, pp. 568-581, September 1911.

ment work is not large. The Virginia mine consists of an open cut or glory hole 120 by 60 ft. in plan 35 ft. deep. From the open cut the workings of the first level extend, and 25 ft. deeper are those of the second level. In addition, there are a number of shallow shafts and twelve diamond-drill holes from 88 to 400 ft. deep.

Geology of the Deposit

Perhaps the oldest rock of the region is a dense white (less commonly pink) quartzite, outcropping about a mile east of the mine buildings and encountered at the bottom of several diamond-drill

of yellow and red color; of soft red sandstone; and purplish brown shale. Some 5 miles west in the deeply carved mesa, between the foothills and the desert valley, the 'red bed' series reaches a thickness of at least 500 ft. The relative amount of arkose and sandstone increases westward at the expense of the conglomerate. Platy gray limestones and limy shales, believed to be of Cretaceous age, lie presumably unconformably, on the 'red beds.' These rocks, which are at least 400 ft. thick, form the hills enclosing the basin within which the orebodies occur. Of still later age are an old talus and a residual formation of coarse partly consolidated conglomer-

FIG. 1. SECTION NORTH OF OPEN CUT, SHOWING RELATION OF ROCK TO ORE.

holes. It resembles what elsewhere in New Mexico is Cambrian quartzite, but at the one point where a poorly exposed contact was seen, the diorite appears to be intrusive in it. The quartzite is, therefore, probably of pre-Cambrian age. Of the four considerable areas of diorite of supposed pre-Cambrian age, three are situated near the Virginia mine. The rock when fresh is a dark reddish gray to green, medium grained, quartz-diorite. The texture under the microscope varies from granitoid to porphyritic, the constituents being plagioclase, hornblende, biotite, augite, magnetite, orthoclase, and quartz. At the open cut the upper 20 to 40 ft. of the diorite is soft and of a light gray or pinkish color. This phase is probably in part due to magmatic differentiation, but largely to mineralization and weathering, the latter not only being that of the present day, but also that of an ancient time when the diorite was before exposed to the elements.

Lying unconformably upon the evenly worn surface of the diorite is 50 to 85 ft. of sandstone, a section of which from the top down may be generalized as follows:

	Feet.
White or yellow fine-grained sandstone, containing locally a lense of limestone; frequently cross-bedded	30 to 50
Yellow sandstone, blotched with brown.....	10
Brownish gray sandstone	5
Green sandstone with lenses of green shale, fossil shell fragments locally present, frequently contains malachite	5 to 18
Dense brown blotched sandstone, locally absent.....	1 to 2

This sandstone series, presumably of Carboniferous age, is overlain unconformably by a series of 'red beds' which, within the company property, situated as it is well up in the foothills, are but 90 ft. thick. They consist of red conglomerate containing well rounded pebbles and boulders (6 in. or more in diameter) of diorite, quartzite, sandstone, and a porphyritic rock; of fine and coarse-grained arkoses

ates (Quaternary or late Tertiary in age), and the loam, sand, gravel, and clay (recent) of the present Tularosa river.

An igneous rock of similar mineralogie and presumably chemical composition to the supposed pre-Cambrian diorite, is probably of Tertiary age. It is a light gray hornblende andesite, sometimes porphyritic, composed largely of hornblende and plagioclase with some orthoclase, augite, and magnetite. It intrudes the Cretaceous rocks around Bent in a complex laccolith consisting of a number of approximately parallel intrusive sheets and it cuts as dikes the 'red beds,' not only of the company property, but also of the mesa to the west. The Cretaceous limestone near the larger andesite masses is metamorphosed to a marble, and at one place magnetite, probably derived from the andesitic intrusion, replaces a calcareous shale.

Geological Structure

In pre-Tertiary times, in the vicinity of Bent, there appears to have been a canoe-shaped antiline coursing slightly north of west. The contact of ancient diorite and the underlying quartzite, dips north of west about 11°. The apparent thinning of the pre-Cambrian diorite sheet-like mass to the south of east, as indicated by drill-holes, is perhaps due in part to erosion prior to the deposition of the Carboniferous sandstone, but largely to erosion between the periods of deposition of those beds and the 'red beds' (see Fig. 1.) The intrusion of the Tertiary andesite laccolith pushed up the younger rocks with the mine workings as a centre. The 'red beds' and Cretaceous limestones, therefore, dip away from the glory hole. Near the intrusive masses these dips amount to 45°; one-half mile west the dips are reversed. Some of the ore lenses are displaced by horizontal faults.

The copper deposits are of several varieties, including: (1) lenses in the upper part of the

diorite; (2) ore stringers, extending from the diorite into the Carboniferous sandstone; (3) bedded ores in the Carboniferous sandstone; (4) detrital ores in the wash above the ore lenses. In addition, bedded deposits and veinlets occur in the 'red beds' west of Bent.

The stockwork of lenses which occurs in the upper portion of the pre-Cambrian diorite is the most important commercially. As developed to date, these lenses are on and slightly to the south of the nose of the anticline mentioned. The lenses are from 2 to 18 or more inches wide and strike in all directions. Many are practically vertical, standing at right angles to the upper surface of the diorite mass. Most of them occur in the upper 25 to 40 ft. of the diorite and with depth they become fewer and narrower and contain less copper. Fresh diorite from a depth of several hundred feet, however, shows stringers of ore. Between these lenticular bodies, in the upper 55 ft. of the ore-bearing diorite, is considerable finely disseminated chalcocite, which resembles that of the 'porphyry' coppers. The diorite between the lenses is usually soft and altered, with some masses of hard and unaltered rock. In depth the altered rock is replaced by fresh diorite and below 30 to 55 ft. the altered form only occurs along fractures.

At the time of examination (early in 1912) the more highly cupriferous area appeared to be tabular in form and to lie at and below the top of the diorite. It dips 30° to the west, averages 35 ft. thick, and in plan is triangular, being 350 ft. in one direction and 200 ft. in another. Unfortunately, cores from holes outside of the above area have been lost, but fragments indicate that the commercially mineralized area may be considerably larger. It is reported that further drilling will soon be begun. These lenticular bodies consist of chalcocite with little gangue, and, in many instances, show an incipient crustification. One vein has from the walls in (1) one-half inch of banded quartz, (2) one-quarter inch of chalcocite, (3) 3 inches of barite in the centre.

Chalcocite

Chalcocite, which is believed to be original, is by far the most important ore, although malachite is also present. Azurite, chalcopyrite, zincblende, and pyrite are sparingly present, and native copper and cuprite are reported. The copper ore in the lenses is associated with considerable barite, and some quartz, calcite, dolomite, and siderite. Secondary gypsum is found near the surface. Molybdenite was noted at several places. Calcite usually appears to be distinctly younger than chalcocite, and barite is usually younger, although sometimes older. Veinlets of chalcedony in the diorite do not appear to be connected with the ore deposition. Vugs occur in these lenses and both this ore and that of the veinlets in the Carboniferous rocks, to be described later, were deposited in open spaces.

The ore contains about \$3.50 in precious metals to the ton of copper. The silver value is about 0.138c. per pound of copper, and the gold 0.04c. Silver is presumably contained in the chalcocite. The copper and silver contents increase and decrease together.

The following are smelter returns upon typical hand-picked ore from the lenses:

Copper.	Silver, oz.	Insoluble.	Silica.
10.75	41.2	26.6
32.90	1.90	17.7	...
51.30	2.75	7.4	...
Iron.	Lime.	Alumina.	Sulphur.
4.4	11.0	9.6	2.8
2.8	10.7	...	8.6
7.7	13.9

These larger lenticular bodies appear to stop with the upper contact of the diorite, and no large bodies of ore are known to extend into the overlying sandstone. There are, however, veinlets of barite and chalcocite in the diorite, and a black lustrous hydrocarbon is found at the contact and extends upward into the overlying Carboniferous sandstone. The hydrocarbon, which appears to have been much more

FIG. 2. SANDSTONE WITH GRAINS OF MALACHITE.

abundant when L. C. Graton visited the camp, is probably confined to these veins. These veinlets are believed to be younger than the lenses. The younger age is indicated by the fact that in blocks of an intraformational (?) limestone conglomerate, presumably part of the same sandstone members, are pebbles of mineralized, green, shaly sandstone and cupriferous diorite, the limestone itself being cut by stringers of barite, calcite, and chalcocite.

In the green shaly sandstone at or near the base of the Carboniferous (?) sandstone is malachite and some chalcocite, particularly in the more clayey laminae. This appears to replace the argillaceous lenses and the calcareous cement of the sandstone. There are also in the sandstone beautifully rounded grains of malachite (see Fig. 2), which were presumably chalcocite grains originally, or perhaps malachite grains derived from the erosion of the chalcocite lenses in the pre-Cambrian diorite. This shaly sandstone, where mineralized, carries from 0.1 to 6% copper, and portions of it will be a good milling ore if the malachite changes to chalcocite with depth.

Malachite and azurite in irregular blotches replacing the calcite cement or along bedding plane and vertical fractures, occur in the light colored sandstones at the top of the supposed Carboniferous

rocks. The malachite and azurite are locally concentrated in globules the size of peas, a frequent texture in such ores in sandstone.

The 'Red Beds'

The 'red beds' within the Company's property contain no known commercial copper, although some of the diorite boulders in the arkoses are malachite-stained, probably as a result of the earlier period of mineralization. In the 'red beds' of the mesa about five miles west of Bent, along Coyote cañon, however, are typical sandstone copper deposits, occurring at least at three horizons, one of which is 10 ft. thick. The copper minerals are almost wholly confined to the gray sandstones and conglomerates interbedded with the 'red beds.' The extent of these copper deposits is unknown, but they are probably lenses of comparatively small lateral extent. The copper ore, chalcocite with some malachite, occurs as small bodies, usually one-quarter inch in diameter, replacing the cement (frequently calcite) of the sandstone. Chalcocite also replaces fragments of vegetable matter, a pulverulent lignite, which are fairly common in the gray beds. Gypsum is associated with chalcocite, and at one place a little lustrous hydrocarbon similar to that occurring at Bent was observed. The 'red beds' are cut by dikes of hornblende andesite, and along one of these is a thin vein composed of barite, calcite, and chalcocite, and secondary malachite. This veinlet is either contemporaneous with or younger than the andesite dike and presumably its genesis is connected with the andesitic intrusion. It is probable that none of these beds are workable, but they are of interest in interpreting the probable genesis of the copper ores of the region. Partly rounded masses of copper glance, coated by malachite, occur in the wash above the diorite on the southwest side of the glory hole of the Virginia mine, and some ore was sorted from the soil here.

Genesis of the Ores

The above data are believed to indicate that the Tularosa copper orebodies are complex in origin. It is probable that copper minerals were deposited by heated waters from two rocks of rather similar composition: the one a diorite of pre-Cambrian age, and the other an andesite of Tertiary age. Further, that the copper ores of the Carboniferous sandstone and the 'red beds' are of different origins, that at the base of the Carboniferous series being at least partly of detrital origin, and that in the 'red beds' the copper minerals were probably deposited by replacement through waters dependent upon the intrusion of the Tertiary andesite.

The supposed genesis of the orebodies may be outlined as follows: The diorite in pre-Cambrian times was intruded in some rock which has since been removed by erosion, the ore horizon being approximately the original top of the diorite mass. When the rock cooled, fractures were formed at this horizon and magmatic waters deposited therein, chalcocite with some barite, quartz, calcite, dolomite, and siderite; simultaneously these waters saturated the diorite between the fractures, and not only altered it, but also deposited therein, by replacement, some disseminated sulphides.

When the euphriferous diorite was bared by Paleozoic erosion, it was weathered, and copper, either as elastic chalcocite, malachite, or native copper grains, was probably concentrated at the base of the Carboniferous sandstones in the green shaly sandstone member. Some of the well rounded malachite grains are larger on the average than those of the associated quartz grains, but as the sea was probably comparatively shallow and the deposition presumably rapid, sorting may not have been carried far.

Copper Placer Deposits

Certain gold deposits are known to be ancient placers, and it appears highly probable that copper deposits may be of similar origin, although presumably they are of less common occurrence. Certainly, modern copper placers exist on a small scale. Well rounded pebbles of native copper occur in streams draining the country in which the orebodies of the Chino Copper Co. at Santa Rita, New Mexico, lie. About five years ago Mexicans mined a considerable quantity of copper nuggets from the stream west of Romero hill, and work only stopped because the foundations of houses on the stream banks were being undermined. At Bogoslovsk, in the Northern Urals, Russia, beautiful rounded pebbles of euprite, partly altered to malachite, and with a core in many instances of native copper, are frequently found in sluicing gold. Pebbles of native copper are fairly frequent in streams in many parts of the world, having been reported from the Copper river, Alaska; Malaguit river, near the Paracale goldfield in the Philippine Islands; at Santa Catalina, in the northern part of Argentina; in several creeks in British Columbia; and in Turkestan. The presence of residual masses of chalcocite in the soil above the glory hole at Tularosa demonstrates the possibility of the concentration of copper minerals in sedimentary rocks by erosion. Later, waters accompanying the Tertiary andesite intrusions apparently formed the veinlet observed along one of the dikes in the 'red bed' mesa to the west of Bent, and presumably also deposited the copper ores of the gray sandstone layers in the 'red beds.' It is also probable that the same waters mineralized for a second time the rocks at Tularosa, forming the smaller chalcocite-barite-carbonate-quartz-asphaltic veins which extend from the diorite into the Carboniferous sandstone, for this was a plane of maximum movement in pre-Tertiary time. They probably increased the copper content of the green shaly sandstone. Since then chalcocite has been altered superficially to malachite and to a less extent to azurite. By the erosion of the chalcocite lenses, fragments of that ore have in recent time lodged in the soil immediately above bedrock at the open cut.

Of the \$420,447 in gold and 842,018 oz. of silver in bullion produced in New Mexico in 1912, the cyanide process yielded \$383,698 in gold and 841,575 oz. of silver, the remainder being recovered by amalgamation.

Coke output of West Virginia in 1912 was 2,465,986 tons, valued at \$4,692,393.

Slow-Speed Chilean Mill Data

By ERICH J. SCHRADER

The following data were obtained through correspondence with actual operators of the Lane type of slow-speed Chilean mills. The use of the mill was being investigated in connection with the remodeling of a cyanide plant in Nevada. The present plant consists of a 100-ton dry-crushing and leaching installation, which did not prove successful for various reasons, but chiefly because the sets of Humphrey rolls employed did not crush fine enough. Clay in the ore prevented leaching, and so it was planned to install a grinding machine to be fed by a coarse roll product, and to classify the pulp from the grinder into sand and slime and treat these separately in accordance with the best modern practice.

All-Sliming Mill

However, extensive tests proved that the best extraction could be obtained by 'sliming' everything, and it was decided to erect this type of mill. In the meantime letters had been written to numbers of users of the Lane mill, which was one type of grinder under consideration, and replies were received from most of these giving results with some details. These all tend to show that the Lane would be an efficient machine where an extremely fine product was not desired.

tires were still in good condition. Unfortunately for my purpose, all the replies were from operators that used the mill chiefly as an amalgamator. In one plant, however, the mill was fed with a 1-in. product of a Dodge crusher and the pulp from the Lane mill went directly to cyanide vats.

All of the operators heard from advised feeding the Lane directly from a crusher, and those who were still using stamps stated that they contemplated discarding them and feeding the Lane mill from a crusher. One operator stated that he had not been satisfied and could not get the capacity required, and that the mill made too much slime for his purpose. Unfortunately, he did not go into details as to his experience with the mill.

Only two operators used screens; the fineness of product was entirely regulated by height of discharge.

All agreed that the Lane type of mill was an excellent amalgamator, a good fine-grinder, and that the cost of repairs was low. Others stated that the installation cost less, the water consumption was less, and the first cost was lower than stamps of the same capacity. It seems evident that there is a field for Lane mills as intermediate grinders between crushers and tube-mills, and I would be glad to know if it has been used for that purpose in modern cyanide plants.

Tabulated results obtained from the operators heard from are given below.

LANE SLOW-SPEED CHILEAN MILL DATA							
Data.	1	2	3	4	5	6	7
Size of mill, in feet	7	10	10	7	7	10	10
Time in actual operation	A	2 yr.	3 yr.	G	8 mo.	18 mo.	K
Capacity, tons in 24 hours	24	40	55	14	20	30	45
Horse-power required	7	10	12	?	7	10	8
Gallons of water used per minute	M	B	D	?	?	15	few
Height of discharge, inches	4	4	7	?	6	7	7½
Mesh of screen, if any	30	8
Character of ore	med.	hard	soft	hard	?	hard	med.
Mesh of discharged pulp	44	40	E	H	I	J	L
Time shut down for repairs	5 dy. p. mo.	C	2 hr.	?
Cost of repairs per ton	5c.	5c.	F	?	3c.	5c.	4c.
Size of feed, inches	1½	1	1½	1½	1½	1	1
REMARKS							
A—Total crushed is 8500 tons.			H—80% is minus 100 mesh.				
B—Same as a 10-stamp mill.			I—95% “ “				
C—Repairs made while cleaning up.			J—68% “ “				
D—Have an unlimited supply of water. No record kept of consumption.			L—73% “ “				
E—90% is minus 100 mesh.			K—Milled a total of 7000 tons to date of writing.				
F—Lower than stamps.			M—16,000 gal. per 24 hours.				
G—90 shifts to date.			Where not otherwise stated, no screens were used.				
1In Arizona. Considers Lane better than stamps. Feed direct from crusher to Lane mill.							
2In southern Nevada. An excellent fine grinder and amalgamator.							
3In Idaho. An ideal amalgamator; 81% caught in the mill itself.							
4In California. Not satisfied. Grinds too fine. Capacity limited.							
5In Idaho. Better than stamps as a crusher; less wear and less water needed.							
6In Nevada. Ore extremely hard; free milling; 80% of pulp through 60 mesh.							
7In Texas. An excellent machine for fine grinding.							
The above data were obtained in August 1912 from correspondence with companies actually operating the mill.							

It is necessary that the mill be set on a good concrete foundation which has been carefully leveled. One manager stated that by settling the pulp and using the water over and over again he had a loss of only 180 gal. per ton of ore treated. It is apparent from this and other letters received, that the capacity and the fineness of product is directly proportional to the quantity of water used up to certain limits. Another writer stated that he had milled 7000 tons without any repairs and the

The value of the mine output of gold, silver, copper, lead, and zinc in New Mexico in 1912, according to Charles W. Henderson, of the United States Geological Survey, was \$8,527,955, as against \$2,704,843 in 1911, an increase of \$5,823,112.

Sulphur production in the United States was 3147 tons in 1900, or 2% of the quantity consumed. In 1912, the domestic output was 303,472 tons, or 91% of the consumption.

Hoisting at a Chinese Mine

Wherever possible, the Chinese work their coal mines through entries, which sometimes extend for great distances underground. In some cases head-frames after the foreign model are used, as shown in the accompanying illustration of the head-frames at a North China coal mine. The shafts are 300 ft. deep, 9 ft. in diameter, and are lined with cut stone masonry. One small double-drum hoist serves the two shafts. From one shaft is hoisted coal, in baskets containing 300 lb. and from the other water in raw-hide bags, as shown in the illustration to the right. At mines which are more primitive in their equipment, a Chinese shaft windlass is employed. From sixteen to twenty men are used to turn these. The heavy blocks of wood on the handle frames act as counterweights. The lower picture shows a Chinese hoisting and underground transport system. Each coolie carries from 150 to 250 lb. of coal, in baskets slung on a pole over his shoulder, and walks, continually bent over, along narrow passages. This photograph was taken at the mouth of the mine. It might be supposed that this is an expensive method of handling the material, but as a matter of fact it is the cheapest that can be employed. In the construction of railway embankments, for example, it has been found that a gang of coolies provided with baskets and the *lan-tze* or carrying pole, will move earth at a lower cost per cubic yard than any form of mechanical equipment. Where the mine can be opened through adits and the ground stands well enough to allow openings of sufficient size to be made, this is an excellent method of hoisting and transport combined, as the coolies walk up inclines. Where the dip is steeper a single basket, carried on the back, is employed. Rehandling has to be avoided as much as possible in the case of coal, as nearly all Chinese coals are rather friable, and lump coal is at a premium. It must be remarked that the upper illustrations are scarcely typical, since it is only rarely that timber is used so freely in Chinese mining practice. Except in Manchuria large timber is scarce and expensive, and as a result methods of mining have been developed requiring but little timber.

Underestimating the Cost of Milling Plants—II

By A. SYDNEY ADDITON

At the next property visited, operations were upon a somewhat smaller scale, but at this plant also the management had had experience in plant installation. Here the superintendent was a part owner; an intelligent man who had been successful in developing the mine, and who had some experience in the operation of gold mills. He was well pleased with himself and what he was doing; was an excellent host and talked freely about his property, results, and costs. He told me what the plant cost, but did not offer any explanation when I expressed surprise at the amount. My curiosity was aroused, and I secured the information wanted from one of the other owners the next day.

Preliminary Work

For six months prior to the building of this plant, the superintendent had been writing to dealers in mining machinery, getting catalogues, blue-prints, and prices of various equipment. He discussed milling and milling equipment with everyone who came his way, and secured opinions by letter from a number of mill men he knew, as to the best appliances to use. He secured prices of cement, iron, and pipe, and also conducted, with the aid of the assayer, numerous treatment tests on the ore, checking the results by sending a carefully selected sample to a reliable metallurgical laboratory. He visited two or three cyanide plants, in every way posted himself regarding the building of a plant, and then estimated exactly what such a plant as he wanted would cost, ready to run. A meeting of the co-owners was held, everything gone over carefully, and they decided that the plant was within their means and should be built at once.

The superintendent then placed orders for the machinery with the manufacturer of each individual piece, and ordered the lumber, cement, iron, tanks, and plumbing supplies required. In selecting the site he carefully determined the difference in elevation between the mouth of the adit and the flat by the river with a carpenter's spirit-level, straight-edge, and plumb-lines. The horizontal distance was also determined. Then by figures taken from blue-prints, and tables in catalogues of dimensions of machinery, he determined how much horizontal and vertical room was needed. From these two sets of figures he found that he had just room, by allowing no height at the end of the grizzly on the breaker floor, to put the plant in where he wanted it, above high water. Excavations were started and the cement retaining-walls and mortar-block built. He had neglected to ask to have the holding-down bolts for the mortar sent ahead of the mill shipment, so he bought iron locally and made them, improvising pocket washers in order not to delay the work on the mortar block. This, and the use of nearly double the lumber and labor expected for forms for retaining-walls and mortar-block, were the first items of excess cost.

In framing the ore-bin there was considerable waste of lumber and labor, especially in the lining, on account of the 2 by 12 and 1 by 12-in. lumber having been ordered by so many thousand feet, without specifying lengths necessary. When the rock crusher had been set it was found that the feed opening was 18 in. higher than prepared floor level, due to the height of breaker being 6 in. more than was expected and a set of sills across the ore-bin caps to carry the breaker having been overlooked in original figures. So to avoid having to lift all the ore with a shovel to feed the crusher, and also to avoid an up-hill tram from the mine to the mill, an equivalent amount was cut off the grizzly. The bars had to be taken down, carried to shop, cut, and drilled, the frame rebuilt, and the grizzly replaced.

Next, when the mortar was moved to its place on the block, it was discovered that the template used for setting the bolts had been incorrect, or at least did not correspond with the holes in the casting, and also that the base of the mortar was heavier than expected, so that the bolts were too short by an inch. Many plans were discussed for getting over this trouble, but it was finally decided that the best thing to do was to blow the block out and make a new one. Miners skilled in the use of explosives were brought from the mine and put at the task and cement was ordered, while the construction crew went on with the rest of the plant. The taking out of the mortar-block was accomplished with but a few hundred dollars damage to building, walls, and ore-bin foundations. While the new block was setting, work was pushed elsewhere.

Floor Levels

Below the plates was placed a set of spitzkasten for classifying the pulp for concentrating tables. In establishing the level of the concentrator floor below the plates the fall allowed below the spitzkasten was barely sufficient to cause the stream to flow to nearest table. As the tables were all placed to one side of the centre line, an additional 2 ft. was necessary. Hence the stream must be raised or the tables lowered, and as the first was impossible without pumping, the latter was done. As the wooden concentrator floor had already been laid and the tables set up, this necessitated moving the machines to one-half of the floor while the other half was torn up, excavation deepened, and the floor relaid. The same was then done to the other half. The expense of doing this was heavy, as the excavation was mostly in rock, much lumber was wasted in tearing out the floor, and the building had to be patched at the bottom of the walls. The alteration meant that all the levels below the concentrator floor had to be lowered a corresponding amount. Fortunately the leaching vats had not yet been erected, although their foundations were in. These foundations had to be lowered; the settlers for the slime plant, already erected, knocked down and their foundations

lowered; the grade for the leaching vats cut down, not a small job, and in fact nearly everything that had been completed below had to be done over again. By the time the sump level was reached it was found that an excavation of nearly 3 ft. had to be made below the high-water mark of the river, and as the flat extended up stream some distance, a levee 500 ft. long had to be built to hold back the water from flooding the sump level. A cement floor and a 2-ft. wall were also built to protect the sump and pumps. A third order of cement was made for this purpose.

Timber Framing

The mortar-block once more ready, the battery frame was erected, when it was discovered that an error of 1 ft. had been made by the carpenter in framing the posts for the ore-bin, on account of not having detailed drawings to work from, so that the knee-timbers did not take the battery posts where they should. This also affected the fall from ore-bin gates to the ore-feeders. The battery posts were reframed to fit and a new opening made in the ore-bin, 1 ft. higher, thus lessening the capacity of the bin. In constructing the building, lumber and corrugated iron had to be ordered three times, not having been carefully specified in orders. This was not only on account of shortage of amounts, but on account of shortage of the sizes and lengths necessary. The bookkeeper told me that at least 14 orders for pipe and fittings had been filled during construction, and that the light team had been almost constantly on the road between the plant and the railroad, bringing in rush orders of small items. The item of freight for this installation was astonishingly large. Each piece of machinery had been ordered from a different house, so that all except the stamp-mill itself had to come in less-than-carload shipments. This was also true of two of the lumber orders and two cement orders.

The excess cost of this mill is hard to specify. The extra labor and material used in alterations can be easily computed, but this was but a portion of the added cost. The time lost in discussing the best way out of the difficulties, the shifting of work from one part of the construction to another nearly every day, the extra cost of hauling and handling material, telegraphing, teams on road all the time, and so on, are all items of cost which are hard to estimate. An idea of the amount of these unmeasurable losses was obtained by adding the cost of additional material purchased, labor employed in alterations, and the excess labor cost on regular construction to the original estimate. The actual cost of the completed plant exceeded the corrected figures by more than \$2000, the difference representing this, that, and the other items that could not be otherwise estimated. The original estimate of the cost of this plant was \$56,200; its actual cost was \$69,860. Here nothing could be blamed for the excess cost except the lack of carefully prepared plans and working drawings from which to build, and from which to order material and equipment. The conception of the plant was good, the equipment purchased was all right, and its cost came within the estimated cost, but the failure to spend a few hundred dollars

in properly preparing for construction work proved expensive.

At the next property I arrived at a most opportune time. A cyanide plant had just been completed, but no satisfactory results could be secured. The owner and general manager were, when I arrived, in heated argument with the engineer in charge. They were denouncing him in the strongest manner, and though he seemed to have some defence, nothing would satisfy the owner. My first impulse was to pass on, not wishing to be drawn into an argument which gave every sign of becoming of a personal nature. I was interested, however, for here seemed to be a chance to secure good data for my investigation. Therefore, when the owner said he would like to have me run down the trouble, an arrangement with which the engineer seemed particularly well pleased, I agreed to do so. I first looked over the plant, which consisted of a stamp-mill, concentrator, and cyanide leaching equipment, well arranged and built. I soon found the difficulty to be a mechanical one; the pulp simply would not leach. Upon examination of the pulp and the ore in the mill, the trouble was apparent enough; so apparent that I could not understand how such an error had been made. The engineer I knew by reputation, and had no reason to doubt his ability as a metallurgist. The company was supposed to have plenty of money and would not be apt to construct an inefficient plant simply because it was cheap. (This, by the way, is often done.) The fact that the ore was of such a character as to require regrinding and sliming was obvious, and I felt as though I had been employed simply to verify the owner's opinion of the engineer.

Mill Design

However, my curiosity was aroused and I determined to run down the cause. I asked who had devised the treatment and designed the plant. The engineer had designed the plant, or specified the equipment, basing his work on the report of a reputable metallurgical laboratory after testing of a 2-ton ore sample sent them by the owner. I examined the report, which was complete and thorough, but the ore tested could not possibly have been the same as was then in the mill. I called their attention to this, whereupon I was advised by the owner that there could be no doubt as to this point, for, being desirous that no error be made, he and his manager had personally taken and shipped the samples, using the greatest possible care in so doing. I then proposed a trip to the mine. When we reached the first heading I found the solution of the problem, but visited other parts of the mine before voicing my opinion. The sampling had been done in the following manner: at ten places in the mine, some headings, some stopes, the ore had been well cleaned down, a floor of plank laid, a round of short holes shot in each place, and a 400-lb. sample sacked. The owner explained just how they had done this, and how careful they had been. At many of the places no work had been done since the sample was taken, and the floors, covered with what ore they left, was still to be seen. This is what had happened. The vein, which was 6 to 10 ft. wide, carried streaks

of nearly pure clay, some 1 in. wide and some as wide as 9 in. At one place where the vein was 80 in. wide, the added width of these clay seams was 19 in. After the cut had been made they had put the ore into the sacks with their hands, as evidence of this, masses of clay, which should have gone into the sacks, were lying on the floor. They had taken only the nice clean ore, and such clay as might stick to the pieces or be gathered up when they took an occasional scoop of the fine ore which, by the way, would contain very little clay, it being too sticky to break up small. Hence, instead of having to treat an ore, which, according to the test made, could be crushed to 30 mesh with only 18% of slime, they had an ore which when crushed to 30 mesh yielded 40% of slime.

Testing the Ore

The owner was, of course, greatly chagrined at this disclosure, and although he said that he saw the point, he did not like to talk about it. Next morning he asked me what he had better do. Of course I told him that an examination of his ore would be necessary before it would be possible to specify just how his plant could best be remodeled. One of two things was necessary: either sliming of everything with a proper plant for treatment, or separating the slime from sand, using the present equipment for the sand and adding a small slime plant. The knowledge that he had himself to blame for his present trouble, added to the fact that he was about out of funds, did not tend to put the owner in the best of spirits. He was inclined to blame everyone in sight, discharged the manager, and started East to raise more money with which to remodel the plant. I afterward learned that he had later tried one or two patent schemes, with the usual results, and finally built a first-class plant. I have never seen this, but have noticed in the mining journals that it is operating successfully. The plant at the time when I was there had cost approximately \$30,000 (exclusive of the stamp-mill). The plant that he should have had in the first place would have cost approximately \$60,000, no doubt about what the present equipment cost, reckoning the first construction as a complete loss. This together with the cost of experimenting with the untried, between times, doubtless ran the excess cost of the plant up to \$40,000.

This is an example of excess cost due to employing an engineer to design and install a plant for the treatment of ores that he has not personally tested. To insure success where it is necessary to depend entirely upon an engineer's advice, a competent man should be engaged, who will examine the ore for treatment and design and erect the proper plant. It is then up to him, and the owner has eliminated all chance of failure except one, the selection of the right man. By proceeding as in this case, two chances for error are directly invited, and indirectly many more. The engineer was also to blame, since he should never have accepted an engagement to design and construct a plant without making a personal examination of the ore to be treated. This case may also serve as an excellent example of excess cost, due to unintelligent sampling of the ore to be treated.

Second-Hand Machinery

The next case was interesting on account of the way I happened to come in contact with it, although it has been, and probably always will be, a common one. While traveling on the train one day I met a mining operator and owner with an engineer whom he had just engaged to construct a plant. We engaged in a discussion of mills and milling practice, during which I chanced to make some remark about the inadvisability, as a rule, of installing second-hand machinery, and soon found out that I was being drawn out on this subject. Not being adverse to giving reasons for my opinions, I acquiesced. Finally the owner said I might be right in some cases, but that he was then taking his engineer to look over a mill that had been closed down for some time, in order that he might determine what additional machinery would be necessary to add to this equipment, which he intended to buy to complete his own plant. He believed that my reasons would not hold good in this case. I agreed that they might not. In speaking of this mill they were going to examine he said there were, of course, a number of parts for which he had no use, others that would require overhauling, and still others that would have to be 'adapted' (how little he knew the meaning of 'adapted'), but he was getting it all so cheap that he was making a great saving in the cost of construction. The engineer did not altogether share his employer's views, and frequently took my side of the arguments.

Recently I had an opportunity to learn the history of this installation. The engineer had refused, after inspection of the old mill, to use it as a part of the new plant. Another engineer was secured, who was willing to build anything that suited the owner. The mill was bought, wrecked, and moved to the new site. The freight charges on this material, owing to the situation of the mill and the quantity of junk moved that was not wanted, was nearly double the amount that would have been charged on new material. In addition to this equipment there had been purchased from wreckers and second-hand dealers, a tube-mill "as good as new," two sets of rolls, designed for roughing, "but could be speeded up," a classifier, several large tanks of various sizes, "that would work in," pumps, gasoline engines, a job lot of shafting, pulleys, belting, pipe and fittings from another old cyanide plant, and so on. The only new equipment purchased was two thickeners and a filter.

Crushing Plant

The crusher, after securing new shoes, dies, liners, and toggles, and re-babbiting the bearings, was all right. In tearing out the ore-bin they found that the frame had been put together with so many drift-bolts that it cost nearly as much to wreck a stick of timber as it would to buy it new, so that only a part of such timber was saved, and practically none of the lining. The mortars were of such an old design that when they sent to the dealers (each of the two mortars being made by a different iron works) for parts, they found that these would have to be made to order. The patterns also had to be made,

for since the iron works had abandoned that model of mortar they had destroyed the patterns and carried no stock of the parts. The stems had to be turned to fit heads and tappets that could be purchased from stock. The rolls had been designed for dry crushing, and had to be 'adapted' to use as regrinders by having a new water-tight housing designed and built. The classifier had been left, when last used, filled with pulp, and all the submerged parts were destroyed, requiring new.

Changes and Renewals

The tube-mill was of an old design, so that the new liners and feed-end casting, which were necessary, were obtained only at considerable expense and loss of time. The agitators were found, after trial, to be unsuited to the ore and had to be taken out and replaced by new ones, including the compressor plant for same. The odd tanks which were to "work in" for pulp storage and solutions were found, on account of their size or depth, not to be of as much use as counted on. Much labor was wasted in trying to work over old pipe and fittings, shafting, pulleys, and belting to suit the requirements, resulting in increasing the size of the junk pile and making the purchase of new material necessary. It not infrequently proved that the cost of labor expended in trying to straighten a sprung shaft, or to make some other piece of junk fit for use, is greater than the price of new material, plus the freight and cost. The centrifugal pumps all had to have new runners, shafts, and liners. It was estimated that three-fourths of the building material could be used again, but after wrecking and handling it three times in shipping, less than 40% was accounted for by the time it was used. The cost of taking apart and cleaning the pumps, engines, and other machinery with their rusted nuts and bolts was a large item that had not been counted upon.

The plant was finally finished and started. One of the first things that happened was the breaking of the cam-shaft, the steel having crystallized. Then the main mill motor burned out the first time its capacity was taxed. Numerous other smaller accidents occurred before the plant was really in full operation. The time and labor expended in 'adapting' and 'working in' various parts of the equipment is not easy to estimate, but was great. No details of these items of excess cost were obtainable, but the owner has made the statement that the plant cost him exactly double what he had estimated and a little more than what a new plant would have cost. He has now a second-hand plant, the maintenance of which is a heavy item of expense. The junk pile on the hillside beside the plant represents the money that should have gone into new material and equipment. It is quite possible, sometimes, to pick up at low cost a piece of machinery that has been used that will prove efficient in service, but when it comes to thus equipping an entire plant, especially building material, the task is impossible, and is bound to result in a great excess over the estimated cost.

Installment Method

At another property I found the superintendent very proud of how he had put the mine on a paying

basis in spite of the opposition he had to contend with in his company. This method, as he explained it to me, is an extremely dangerous one; and following it is a common reason for excess cost. He had been developing the property for a company, the resources of which were limited. For some time individual stockholders had been advancing money necessary for continuing work. When the end was in sight, these stockholders did not care to carry the company further, and other ways of raising money were about exhausted. The superintendent told the directors that if they would raise a certain sum of money he could erect a milling plant that would net enough out of the small amount of ore they had developed, to carry on development work. The sum he asked for seemed small, but he explained how it could be done. It was finally decided that they would make this one last effort. They raised the amount and construction work was started, but it was soon found that certain costs had crept in that had not been counted on, and that additional money was necessary. The stockholders must 'dig' again, as they could not stop with the partly completed plant, and thus lose what they had already strained themselves to put in. They raised the amount "necessary to absolutely complete the work," which was, by the way, 30% of the original amount asked for on beginning to build. The plant was finished, but it was found that the results obtained were not those anticipated, and in order to make a profit at all on the ore certain alterations and additions must be made. Again the stockholders were at the point where they must either lose what they had put in or raise more money. After a considerable delay they succeeded in getting together an amount which was 35% of the original sum. One more delay to raise still more money followed, but the money was secured and the plant finally completed at a cost nearly double the amount first estimated to be necessary to put the mill in operation. The owners were not out of the woods yet, however, as the machinery houses which had already extended the time of final payment on equipment refused to wait longer, and a fourth 'dig' had to be made by the stockholders with which to meet this indebtedness. Events such as these have been the history of so many installations that some may wonder why they are recited here. But they illustrate another reason for excess cost.

Lack of Coöperation

The superintendent knew at the time he first went to the directors that the amount he was asking for would only be about half the amount required, but attempted to justify himself by saying that had he asked for the whole amount at the start, the mill would never have been built. It is astonishing to learn how many plants have been built or are being built in just such a way as this. Sometimes the directors are in collusion with the superintendent in deceiving the stockholders, sometimes an engineer desires to extend the period of his employment, but in one way or another this cause for heavy excess is exceedingly common. During my trip of investigation I came across five cases of this kind, and the worst is that four of the five did not end as success-

fully as the one described, as the companies could not raise the additional sum required and had to shut down, losing what they had put in. In this case, the superintendent was extremely fortunate; in the first place, that the stockholders staid by him and were able to raise the additional sums of money, and, secondly, that in his partly developed mine he was later able to develop an orebody which finally justified the plant.

Superficial Examination of the Ore

I next visited a plant that was quite a model of construction and found that it had been built at about the estimated cost. They were, however, having difficulty in getting the hoped-for results. It was a stamp-mill furnished with a cyanide plant; the sand and slime being separated and each treated in a department of its own. It had been built following the design and detail of a neighboring plant, of which it had been possible to get the construction costs. This accounted for its having been constructed within the original estimate. The results, however, were not alike, although the ore was given "exactly the same treatment" and the "ore was the same." One of two things was evident; either the neighboring plant was not yielding the results claimed (which is by no means a rare case), or the ore was not amenable to the same treatment. In this case it proved to be the latter, and upon investigation it was found that the sand must be re-ground in order to secure good extraction. This meant the remodeling of the plant, purchase and installation of much additional equipment and material, and the tearing out of much that had been installed. This was done, resulting in an excess cost amounting to 80% of the original. This serves as an example of an excess cost due to a too superficial examination of the ore to be treated. Because it looked and assayed like that in the neighboring mine it was thought that a plant like the neighboring one was what was wanted.

On approaching another property, the panorama of junk-heaps and badly constructed buildings told its story. I thought I had probably come across another case of a second-hand plant, but I was partly mistaken. The superintendent, who was a half owner and had full charge of the property, in taking me through the plant, excused the general appearance of things by remarking that the mill, having cost nearly double the estimate, he had not been able to do any fixing up outside, as yet. I asked him why the mill had cost so much more than expected. He recounted the longest list of reasons it had ever been my lot to listen to. It seemed as though everything had been 'agin him' from the start. Everyone in his employ had made mistakes, others had lied to him, and he had had innumerable "unforeseen accidents." After I had about made up my mind as to the real cause of this excess cost, I asked who had designed the plant. He replied that at the time he had decided to build the plant he "did not see any use in hiring one of them experts and paying him big wages for doing nothing but bossin'." He knew the treatment necessary for the ore and there were a lot of mills around to "get ideas from," some

of which he had worked in, but he finally conceded that it probably would have been just as well if he had hired someone to "make a draw'n" for him. I said I supposed he realized now that some of the errors for which he blamed his employees were due to the lack of some plan to work from. "Yes," he said, "that is probably true, as I see it now, but I wanted to save the expense; I wanted to build the plant just as economically as I could. You see, my partner is a city man and does not know much about the cost of such things, and is not very wealthy, so I wanted to cut out all the expense I possibly could, as he has had to put up most of the money we have spent on the property." I asked him what his 'city man' thought of his success, but got no reply. In his efforts to economize he had incurred all the added cost of both a mill made without plans and one made with second-hand machinery. He had succeeded in combining both reasons for excess cost in the one mill, from no other reason than that of desire for economy, and not from necessity, as I later learned that his partner would have advanced all the money required. Economy is certainly commendable in any enterprise, but to successfully practice it in the building of a milling plant requires the exercise of the knowledge born of experience.

The Machinery Question

A case investigated later is so closely similar that I will mention it as well. The property was an individually owned mine, capable of producing a fair tonnage of low-grade ore. The grade and character of the ore were such, however, as to call for the best efforts of a capable man, and the use of the most efficient equipment in order to insure a profit. These facts were known to the owner and had the effect of convincing him that he must have equipment which would do a little better than that ordinarily in use, and could be operated more cheaply. When a man starts actually to hunt for such devices, he has but little difficulty in finding plenty "peculiarly adapted to his particular case." The result was, in this case, that after much discussion with sellers of the "very thing he wanted", he estimated what the plant he wanted would cost, and proceeded to install a lot of machinery, most of which had never been tried on a commercial scale. Some had been tried and found deficient, "but had never been given a fair show, on account of certain conditions which were unfavorable." After fooling along with these devices, adding costs every day, for some time, he decided that he did not have just what was required. Then one appliance was replaced by another "just the thing" machine and another appliance had been replaced by some other wonderful contraption of genius. A 'revolutionize metallurgy' device had also been substituted for another machine that was not giving satisfaction. Finally one or two standard pieces of equipment found their way into the plant, and its operation was made possible, although not yet profitable. More than three times the original estimated cost had been spent, and the owner was out of funds. After a year's delay he parted with an interest in the mine to another man who supplied the money necessary to remodel the

plant and put it on a profit-paying basis. This had just been accomplished at the time of my visit. This attempt to use unproved devices rather than following standard metallurgical practice is a common cause of excess cost.

High Installation Cost

The next plant visited, while not exactly an instance of excess cost, furnishes an example of abnormally high cost of installation, which may as well be mentioned here. Most engineers have in their mind what they conceive to be an ideal plant. They long for the chance to construct it. Opportunity does not often come for this, as idealism is generally associated with prohibitive cost, but opportunity did present itself in this case, and an attempt was made to utilize it. A large plant was elaborately designed; every device known was incorporated in the plan. Standard practice and methods of treatment existing in plants from South Africa to California were provided for in different portions of this mill. An elaborate power equipment was also provided. Nothing was left out, everything was perfect when plans were submitted, not accompanied by estimate, this being left to bidders on the work. Bids were received and all were rejected on account of the high cost. The 'idealizing' had been overdone. The plans were then put into the hands of other engineers for revision to cut the cost. No time or money was allowed for these engineers to examine the ore and working conditions, in order to enable them to perform their task intelligently. They simply had to cut here and eliminate there, without knowing whether or not the result would prove to be a plant efficient in treating the ore. They succeeded, however, in getting the cost cut down to a point where the installation was ordered.

Power Service

Of the various additions and alterations found necessary upon starting operations I shall not attempt to speak in detail here. Sufficient to say that the company was certainly fortunate in that more were not necessary. One item deserves mention. It was found that because of the price of coal it was costing considerably more to operate the power-plant than power would cost if furnished from a local power company. So the \$40,000 power equipment was abandoned. I do not know that the dealers and railroad companies refused to quote prices on coal before building the power-plant, but it is hard to otherwise account for such an error. This plant has been in successful operation for many years and has netted large sums to the company. It did not cost more than the estimate, but that it ultimately cost more than the company expected that it would, and much more than it should, is without question. Such instances only strengthen the belief in the impossibility of constructing a plant without exceeding the estimated cost.

Another case of idealizing or "keeping abreast of the times" was found at another property, where a new plant had just been put into operation. This plant was most complete, and a profit was being made which was satisfactory. The plant had been built without any preliminary estimate, but had cost

nearly double the amount that another plant of same capacity and treating the same ore had cost, and the operating cost was greater than that of the cheaper plant. The reason for this was that the designer of the new plant had built an ideal plant, not ideal as to the treatment of the ore, but ideal as to the latest devices in cyanide plants. The 'up-to-date' expensive plant was not required in this particular case. The same net recovery could be made with an 'old-fashioned' simpler plant. New methods and practice yearly widen the scope of metallurgical processes, especially in cyaniding, but it is not always necessary to adopt such methods and practices when old ones will give the same results. It is no crime to be considered 'out of date' if the plant is 'delivering the goods' and saving capital expenditure. This point is worthy of discussion in a separate article.

Recovery v. Operating Costs

A small plant was visited, where everything was apparently running nicely. The equipment was new and the engineer who had built the plant had gone. The metallurgist in charge told me that the plant was good, but the recovery was low. He had conducted exhaustive experiments since he had taken charge, and determined that a higher percentage of the metal content of the ore could be saved by adding to the plant certain machines and altering the method of crushing and treatment. He had ordered what he wanted and said he would soon be making a higher saving. It later developed that he was correct. The plant was remodeled, was quite successful, and the higher recovery was made. In doing this, however, he had allowed his technical knowledge to overbalance his practical knowledge, and while he made a higher recovery he also incurred a higher operating cost, to which could also be added interest on additional investment, until the net was only about equal to the net made by the original plant. The remodeling and adding to this plant was an excess cost due to an attempt to make a metallurgical success, when a financial success was what was most important to the company.

I have mentioned only the most interesting and common cases of excess cost met, though I encountered each of these instances more than once; some of them many times. I saw many abandoned plants, the history of which would show the relation of excess cost to absolute failure, but its relation would add no additional information. I found a number of plants where the excess cost had been caused by such reasons as lack of knowledge of treatment by the designers of the plant; equipment selected and purchased by officers and directors of the company; installations directed by company officials, without making use of the knowledge of their superintendent or engineer; plants rushed to incomplete completion, on account of short funds, or on account of stock-market operations; plants built on low estimates of superintendent, who knew that if he got it started the rest of the money would be raised, thus prolonging his job; plants built for large stock companies by unscrupulous officials, where large portions of the excess cost went into their own pockets.

Topographic Model of Cripple Creek District

By E. A. BYLER and LEE W. DAVIS

The half-tone presented here is of a topographic model of the Cripple Creek district which has been made embracing the territory covered by the U. S. Geological Survey special sheet of this district.

The model is made on a vertical scale of 400 ft. to 1 in. and a horizontal scale of 1000 ft. to 1 in. The data for the topography were taken from the Geological Survey sheet, and enlarged to the scale of the model.

The original model was made of poplar boards of

the sheet. In the photograph these colors have taken as shades and, as will be seen, some of these show quite clearly, while others do not, and they have the effect of confusing to some extent the natural shading due to topography. In the lower left hand corner of the photograph will be noticed a dark strip representing a dike of considerable extent; many such are found in the area covered.

The photograph was taken from the south end of the model and gives, in effect, a birds-eye view of the district looking from a high point at its southerly end. The main producing portion of the district is about in the centre. In looking at the photograph a large reading glass is an aid in bringing out the perspective.

A difficult problem in designing the model was the

TOPOGRAPHIC MODEL.

such thickness that each represented an elevation of 150 ft. Each board was cut to contour with a scroll saw and then placed and glued in its proper position, after which the whole was dressed to conform with the contours. The small changes were interpolated in the topography between these elevations, and some small portions made with putty. The railroads were represented on model by wire placed in the proper position.

Plaster Model

From the wooden model a plaster mold was made, from which in turn a plaster model was cast, thus making a reproduction of the original wooden form. This final cast was painted in various colors and lettered to represent the features which it was desired to indicate. For the purpose of more closely identifying positions by comparison with a map of the district, the section lines were indicated on the model in black and the number placed in the centre of the section. Railroads, positions of the principal mines, towns, and other artificial features, together with the lettering, were in black.

The surface geology, as given by the U. S. Geological Survey sheet, is represented by various colors, following as near as practicable the colors used on

selection of a relative vertical-horizontal scale to properly represent to the eye and mind the topographic features, the difficulty being that the steep slopes would appear to the eye as exaggerated, and the more gentle ones too flat. Numerous combinations of scales were tried, and it was finally decided to adopt a vertical scale of 400 ft. to 1 in. and a horizontal scale of 1000 ft. to 1 in., it being found to be the best average and conveying the most natural impression to the eye.

Sulphur deposits of Park county, Wyoming, according to D. F. Hewett, in Bulletin 540 of the U. S. Geological Survey, lie at an elevation of 6700 ft. along Sweetwater creek, two miles north of its junction with the north fork of Shoshone river. The area does not exceed 20 acres. The superficial rocks nearby are wholly igneous, and constitute the lower portion of a great thickness of lava flows. The sulphur occurs as bands of crystalline aggregates which fill the interstices between the fragments in the bank of the stream where it cuts part of an alluvial 'fan.' Under the present condition of the American sulphur industry, the deposits are not profitable.

Smelting in Shaft Furnaces at Great Altitudes

By VINCENTE PAZOS Y SACIO

*The numerous failures made in Peru in attempts to smelt raw copper ores seem to result from lack of knowledge of the behavior of shaft furnaces at the great altitudes at which they are generally worked. The following hints, deduced from observation and proved by numerical results, perhaps may be found useful by those who have to manage furnaces in such places.

The Problem

The solution of the following problem will give a practical insight on the vital point.

Problem.—What will be the temperature of a water-jacket furnace in Cerro de Paseo where the atmospheric pressure is 8.75 lb. per sq. in.,¹ when the same furnace at sea-level (15 lb.) gives 1365° Centigrade?

By the laws of combustion,

$$1 \text{ kg.} + 11.56 \text{ kg.} = 12.56 \text{ kg.}$$

or 1 kg. of carbon combining with the oxygen of 11.56 kg. of air gives 12.56 kg. of heated gases which produce 8100 kilogram-calories.

Assuming that the coke contains 10% ash; the carbon in each kilogram of fuel will be 0.9; and equation (1) will reduce to:

$$0.9 \text{ kg.} + 10.4 \text{ kg.} = 11.3 \text{ kg.}$$

If the above reaction did not produce heat, the volume of the gases at 0°C. and 76 cm. (15 lb.) pressure, would fill:

$$10.4 \div 1.3 = 8 \text{ cu.m.} \quad (3)$$

But the reaction generates a great quantity of heat, which it may be supposed raises the temperature to 1365° Centigrade.

This temperature has been assumed because it gives an even expansion of the gases, and it is near the minimum at which raw copper ore can practically be smelted.

Since air at 8.75 lb. pressure is lighter than at 15 lb., and as the temperature depends on the relative weights of carbon and air combined in a given time, to burn 1 kg. of 10% ash coke, which at the coast needs 8 cu.m. of air, at Cerro will need in the same time and at the same initial temperature:

$$8 \times (15 \div 8.75) = 13.71 \text{ cu.m.} \quad (4)$$

It is seen that if a furnace is designed to burn, at sea-level, a certain quantity of coke, to fit this to burn the same quantity at Cerro, the capacity of the blowers, air conduits, and the area of the tuyeres must be increased about 70%. If these changes are not made, but the blowers are only run faster, the blast-pressure will increase, introducing evils of which I will treat later, and at the same time the blowing engine will be forced to do a great deal of useless work, increasing leakage at a ratio which will surprise men who have had no experience in

operating furnaces at such high altitudes.

The problem of the volume of air, which now looks so simple, was solved on a scientific basis about 30 years ago. Before this the greater part of those who tried smelting in the Cordilleras blew too little, although some went to the other extreme and blew too much air; but none could tell in a scientific way the amount that should be blown. As up to that time results of shaft-furnace smelting had been unsatisfactory, it became an axiom that "smelting in shaft furnaces is impossible in the high cordilleras of Peru." Engineers of almost all nations had tried it and failed. Percy, in the older editions of his 'Metallurgy,' treats of this subject.

The question now arises, does the same amount of carbon burned in the same time at Cerro de Paseo afford the same temperature as at sea-level? If one cubic metre of the eight (equation 3) is taken, formed by the combustion of 1 kg. of 10% ash coke, and enclosed it in a prism one metre square,

At 0°C. the gases will fill 1 metre of the prism.

" 273°	"	"	2	"	"
" 546°	"	"	3	"	"
" 1365°	"	"	6	"	"

Thus the assumed temperature of the furnace expands the gases to six times their volume at 0° and 15 lb. pressure.

If this is plotted (see diagram) taking the origin of coördinates at O, which represents absolute zero, and making Oy, Ox, represent respectively the absolute volumes and pressures, then the point t_{15} can be made to represent the temperature 1365°C., since the line Ov_{15} represents the absolute volume of 6 cu.m., and the line Op_{15} the absolute pressure of 15 lb. at sea-level. The subfixes of p, v, and t, in the diagram, represent the pressures in pounds to the inch, to which the different pressures, volumes, and temperatures correspond. To find the relative values of temperature, pressure, and volume at any other point, pass a curve of expansion through the point t_{15} .

Rate of Combustion

Since a furnace made for sea-level work by increasing the volume of the blast, can be made to burn the same quantity of coke at Cerro, the rate of burning is the same. As the heat of combustion inside a furnace continually replaces the heat spent, and as the number of heat units, no matter at what temperature, will always be constant, the curve must be an isothermal, no matter how much the atmospheric pressure may vary. In other words, what is desired is to find the quantity of coke necessary to keep a fixed temperature of 1365° at a pressure which varies from 15 to 8.75 pounds.

An isothermic is an equilateral hyperbola

$$p v = P V = \text{constant.}$$

In this case $P = 1$ atmosphere = 15 lb. per inch = 10.333 kg. per square metre.

$V = 6$ cu.m., which is the starting volume at

*Excerpt from the *School of Mines Quarterly*, July 1913.

¹This is the pressure at the American smelter near Cerro de Pasco.

sea-level pressure and at 1365°C. temperature. From the nature of the curve of expansion, it is quite easy to find as many points as wanted. Since $p v = P V$, $v = P V \div p$.

The work done is represented in the diagram by the area bounded by the lines ($t_{15} \dots v_{15}$), ($v_{15} \dots v_{8.75}$), ($v_{8.75} \dots t_{8.75}$), and ($t_{8.75} \dots t_{15}$), which represents a given volume displaced by a certain varying pressure. From the nature of the curve, this area is the same as that enclosed by the lines ($p_{8.75} \dots p_{15}$), ($p_{15} \dots t_{15}$), ($t_{15} \dots t_{8.75}$), and ($t_{8.75} \dots p_{8.75}$), which represents a varying volume displaced between two pressures.

As the first area is the more natural representa-

and under a pressure of 15 lb., is found to be 60%, equal to 1365° Centigrade.

At Cerro, under a pressure of 8.75 lb., owing to the heat lost by the expansion of the gases, the same furnace, with the same weight of air, which means 70% more volume blown in the same time, and with the same weight of fuel, will give only 52.1% efficiency, equal to 1184°C. Thus the furnace at Cerro has lost about 13% calorific capacity, as compared with the same furnace at sea-level. This is on the assumption that the air is perfectly dry. To obtain closer results, it will be necessary to make an approximation to bring the respective temperatures nearer to their true value.

Atmospheric Moisture

At sea-level, owing to the greater pressure and temperature, the air, especially in tropical latitudes, contains a quantity of water vapor which cannot be disregarded; while on the high altitudes of the Andes, the low pressure and temperature make atmospheric moisture very small. At sea-level, the air will be blown at a mean temperature of 25°C., while at Cerro the mean will be 6°, varying during the day from 1 to 11°. Not taking into account the initial temperature of the air at the two places, one can estimate the moisture which, at the coast, has to be heated to the required temperature of 1365° Centigrade.

It is computed that the diminished pressure at Cerro is equivalent to a lowering of 20° in temperature; and the moisture in the air will correspond to that of -14°C., at 76 cm. pressure.

From Renaugt's tables it is found that at this temperature 1 kg. air contains 1.7 gm. water vapor; then the water in the air required to burn 1 kg. of coke at Cerro will be 17.68 gm., or nearly 9% of the water contained at the coast.

Thus nearly 0.9 of the heat units used at sea-level, to heat the water of the air blown into the furnace, is saved at the higher altitudes. As the number of heat units at the coast was 112.7 kg-cal., at Cerro these will be reduced to only 10.1 kg-cal., leaving 102.6 which are saved to be added to the efficiency of the furnace. Allowing 2.6 calories for the heat necessary to bring the water vapor from 6° to 25°, there will be, in round numbers, 100 calories to be added to the efficiency of the furnace at Cerro. The corrected efficiency will be 53½%, as compared with an efficiency of 60% at the coast. In other words, if the furnace at the coast smelts 100 tons per day, the same furnace at Cerro, under the best conditions, will smelt only 89; for the fuel has lost 11% of its calorific capacity. At this temperature only copper ores that have been roasted, and of which the slags are very fusible, can be smelted.

The next question is regarding the effect of a high-pressure blast. Suppose that the blast is 2.19 lb., and assume this pressure is necessary to blow the required weight of air, 10.4 kg. (Eq. 2).

If 1 cu.m. of air at 8.75 lb. is taken and an outside pressure of 2.19 lb. (¼ the atmospheric pressure), applied, the cubic metre will be compressed to 0.75 its original volume; this compression generates heat, but as it is gradual, and as the wind-pipe which

tion of the expansion of the gases, between two given pressures, it can be evaluated by arithmetic. Of course, this valuation, although good enough for practical purposes, is only a rough approximation, for the hyperbolic arc ($t_{15} \dots t_{8.75}$) is considered as a straight line.

Rate of Expansion

Thus 1 cu.m. of the gases of combustion, in expanding from 15 lb. to 8.75 lb. pressure, is found to have done 36,260.16 kg-m. of work. As there were 8 cu.m. of gas (Eq. 3) formed in the combustion of 1 kg. of 10% ash coke, the total for 1 kg. of coke will be:

$$36,260.16 \times 8 = 290,081.12 \text{ kg-m.}$$

As 425 kg-m. = 1 kg-cal., the loss of heat will be as follows:

$$290,081.12 \div 425 = 682.54 \text{ kg-cal.}$$

If closer work is wanted, then the true value for the curve has to be used.

The efficiency of the furnace at the tuyere zone,

connects a blower to a furnace is generally long, the heat generated by this compression is lost through the thin iron shell of the pipe, and when the air reaches the furnace it has the same temperature as the surrounding atmosphere. When the air passes the tuyeres and expands again, practically to atmospheric pressure, for the ore column of the copper furnaces is so low that this factor can be disregarded, the 0.75 cu.m. will not fill its original volume. The heat lost in the compression has reduced its elasticity. In order to get 1 cu.m. in the furnace, one must take 1 metre raised to the 1.4 power, and for any volume v inside the furnace, one requires $v^{1.4}$ from the outside, as expressed in the equation for adiabatic expansion.

Air Required

Equation (4) gives 13.71 cu.m. of air necessary to burn 1 kg. coke at Cerro. The pressure 2.19 lb., which is $\frac{1}{4}$ the atmospheric pressure, will give: $13.71 \times \frac{1}{4} = 10.28$ cu.m. air at an absolute pressure of 10.94 lb. Expanding back these 10.28 cu.m. from a pressure of 10.94 (pressure at Cerro, 8.75 + pressure of blast, 2.19) to a pressure of 8.75, the volume required is 11.78 cu.m. of air.

The work of the gases in this expansion is 29,181.3 kg-m.; and the heat units, $29,181.3 \div 425 = 68.6$ kg-cal., which makes the relative efficiency 52.56% = 1195.5°C. Two pounds of blast additional at these high altitudes will lower the temperature of the furnace about 20 degrees.

At sea-level the furnace has given as sensible heat 4539.4 cal., some of which is lost in the escaping gases. If the gases escape at 500°, 22.8% is wasted and 39.4% is utilized. Then it follows that

2750.6 cal. vanished as radiation, etc....	37.8%
1662.8 cal. wasted in escaping gases.....	22.8
2876.6 cal. avail. for melting (efficiency).	39.4
7290.0 cal.	100.0

To find how much ore this furnace will smelt, and to make the calculation simpler, suppose that only slag is produced. Assuming the average copper slag to melt at 1150°, requiring for this 316 cal., and 90 cal. more to fuse it, the slag at 1220°, which is the probable temperature in the crucible, will take up 419 cal. per kilogram; but each kilogram produces around 43.4 cal. heat of formation.

Amount of Slag

If x represents the number of kilograms of slag formed, then:

$$43.4x = \text{heat of formation of } x \text{ kg. of slag.}$$

$$2876.6 = \text{heat available for making } x \text{ kg. of slag.}$$

$$2876.6 + 43.4x = \text{heat at hand for formation of slag.}$$

$$419x = \text{heat wanted for formation of slag.}$$

Equating:

$$43.4x + 2876.6 = 419x, \text{ whence } x = 7.6 \text{ kg. slag formed.}$$

Smelting matte, the proportion of coke to ore will be more advantageous; and if the proportion is 3 of matte to 7 of slag, 1 kg. of coke will smelt 10 kg. of ore.

Perhaps this treatment of the formation of the slag may be thought arbitrary by many readers:

but a moment's reflection will show that the slag and the gases of combustion cannot have the same temperature. As soon as the slag, in this case, rises to 1150° and gets the 90 cal. necessary for its liquation, it drops into the crucible, and whatever excess of temperature it obtains above this is due to the transfer of heat from a hotter to a cooler body. From the nature of the furnace, once the slag is in the crucible, the ratio of temperature between slag and hot gases must be more or less fixed, since the constant tapping of the slag does not give enough time for equalizing the temperatures.

In estimating the efficiency of the furnace in the higher altitude, it may be assumed that the radiated heat is the same (37.8 per cent).

Effect of Moisture on Efficiency

In the course of this article it has been seen that 100 cal. is gained by the furnace in the higher altitude, by saving the heating of the water vapor; but there is a loss of 626.1 cal. due to the expansion of the gases; thus the net loss is 526.1 cal., or 7.2%. Keeping the same relation between the wasted and available heat, the heat distribution is as follows:

2750.6 cal. vanished as radiated heat.....	37.7%
526.1 cal. vanished in expanding gases ..	7.2
1466.2 cal. lost in waste gases	20.1
2544.2 cal. avail. for melting (efficiency).	34.9
7287.1	99.9

Equating as before:

$$43.4x + 2544.2 = 419x; \text{ whence } x = 6.7 \text{ kg. slag.}$$

By roasting and careful fluxing, more fusible slags can be made, thereby increasing the output of the furnace; but this is expensive, and only rich ores can stand it. This is what is done by successful smelters; the ores are carefully prepared before going into the furnace; and to have a safe margin of heat, the quantity of coke, as well as of air blown in, is somewhat increased, for it is seen that the temperature of the furnace has fallen from 1365° to 1215°, which is not sufficient for the regular operation of smelting copper ores.

It would be tedious to enter further into these details, but the calculations are sufficient to show that, even with the necessary amount of air, smelting is much more difficult at the Andean altitudes than at sea-level; and the man who at these altitudes wishes to work with open eyes must not forget the laws of the expansion of gases.

Pyritic Smelting

To apply the same process of reasoning to pyritic smelting, assume an ore having 70.84% FeS and 29.16% SiO₂.

To make this case as nearly as possible like the one already examined (using coke), consider 1 kg. of fuel, which in this case is the ore itself, and suppose it is converted into slag. From the chemical equation,

From thermophysics it can be deduced that a total of 931 cal. are available to run the furnace.

In coke smelting, the furnace gave a certain dis-

tribution of heat, which will be more or less the same in pyritic smelting; this is:

Per cent.	Calories.
37.8 vanishing heat	352
22.8 wasted heat	212
39.4 efficiency or melting capacity	367
—	—
100.0	931

The slag of the equation will heat up and melt with an expenditure of 395 cal. per kilogram, and most likely, at the crucible of the furnace, will have consumed 406 cal.; thus, $406 \times 0.87 = 353$ cal., is the heat necessary in this case to melt 0.8712 kg. As there are 367 cal. in the furnace, there is an excess of heat above what is necessary to run the furnace.

Distribution of Heat

The heat produced is almost equally divided between the Fe which gives the solid product FeO, and the S, which gives the gaseous SO₂. The O necessary to burn these elements is 0.3864 kg., which represents 1.288 kg. additional N, giving 1.6752 kg. of air, or 1.2886 cubic metres.

The principal data are now available to find the heat losses of this furnace working at Cerro de Paseo, as an atmospheric pressure of 8.75 lb. to the inch. The item lacking is the relative radiation between the two pressures; but as it cannot be had, its value will have to be approximated.

The gases and the solid products of combustion, while gradually losing their temperature in doing the work of heating and melting the slags, will consume, as has been seen, 62.2% of the total heat, or 577 cal. If the temperature to which this 577 cal. will raise its own products is computed, and the heat lost by the gases in expanding from 15 lb. to 8.75 lb. is deducted, there will result the sensible or temperature-making heat which the furnace gives at Cerro.

It can be computed that the fuel constituents of the ore, if not allowed to lose their heat in melting the slag, would, at sea-level pressure, raise their own temperature to 2325°C. The work of expansion is 52,720 kg-m. per cubic metre of gas formed. But as there are 1.20 m., the total work will be 63,264 kg-m. Reducing work to heat, $63,264 \div 425 = 148.8$ kg-cal. Therefore the sensible heat has been reduced by 148.8 cal., and the temperature must be lowered 25.6 per cent.

Making a new distribution of the heat:

Per cent.	Calories.
37.8 vanishing heat of radiation and convection	352.0
14.9 vanishing heat of expansion	142.0
16.9 wasted heat in gases	158.3
29.3 melting heat (efficiency)	278.7
—	—
98.9	931.0

This distribution of the heat is rather arbitrary, for the vanishing heat of radiation is kept the same in both cases. Decreased temperature seems to demand decreased radiation; but, on the other hand, the decrease in atmospheric pressure increases radiation. Not having data on this point, I have thought

convenient to let increased radiation balance the decreased temperature; and if the results are not absolutely true, they will, at least, be relatively so. At any rate, ordinary practice confirms that this assumption cannot be far out of the way.

From the new distribution it is seen that at the higher altitude the smelting heat has dropped from 366 cal. to 278.7; or, reducing to kilogram of slag, from 420 to 312 cal. With this heat no pyritic copper slag can be melted and made to run.

To secure the heat that would be available at sea-level, so as to be able to smelt, add about 4% coke with the corresponding amount of air to burn it; but this addition tends to make poor mattes, for at high temperatures oxygen has a very strong affinity for carbon, as is proved by the bessemer converter, where 2 and 3% carbon is burned without any great oxidation of the iron through which the air blast is made to pass. To counteract the reducing action of the coke, a great excess of air has to be blown; this excess and the consequent increase of the pressure of the blast, cools the furnace, and to remedy this, more coke has to be added. As a result, I have never seen in Peru a shaft furnace trying to do oxidizing smelting and consuming less than 10 to 15% of coke. In Cerro de Paseo, copper ore containing from 6 to 8% Cu is reduced to matte of 40 to 45% with an expenditure of from 10 to 12% coke. At Yanly, the same quality of ore was concentrated to 28 or 30% with a minimum of 12%; and in the smaller furnaces through the country, the concentration is only 2 or 3 to 1, with an expenditure of 15% coke and an immense amount of air blown in. In fact, oxidizing smelting in Peru today is nothing but pot roasting carried to fusion at the expense of fuel. This is but natural since the altitude reduces furnace temperatures, as has been seen, by 11 to 25%, according to the fuel, quantity of air, and intensity necessary for the operation.

Artificial Pressure

In view of all that precedes, I believe that all efforts to do oxidizing smelting in the Cordilleras will be useless so long as they are conducted at atmospheric pressure. But if artificial pressure were put on the furnace, and the fuel were forced to burn at higher pressure, not only oxidizing but real pyritic smelting could be done in the Cordilleras as easily as at lower altitudes. If this were aided by a hot blast, then even ores that at present are thought unfitted for this work could be profitably reduced directly, perhaps with the addition of some coke inside the furnace.

It is true that heavier blowing engines would be required, but although these would have to do more intense work, it is likely that, on the whole, not much more work would be done. At present, the quantity of hot unburned air that escapes up the furnace, due to the small ore columns which are indispensable while working on the present system, must represent a large amount of fuel and power, which, if saved, would be enough to run the heavier machines, while a much cheaper and abundant product would be obtained than at present.

The diagram gives the theoretical temperatures

of a furnace at -6.25 lb. and +6.25 lb., on the assumption that at sea-level the temperature is 1365° C. From this it will be seen that ores which cannot be smelted at an absolute pressure of 8.75 lb. will be easily smelted at an absolute pressure of 21.25 lb., with the same amount of coke and air used in both cases. In pyritic smelting, on account of the greater quantity of air and the higher temperature necessary for the work, the difference will be still greater in favor of the higher pressure, as has already been seen.

Increase in Temperature

There are several ways of increasing the temperature of a furnace:

1. Reducing to a minimum the heavy losses of radiation and conduction; men who are going to use a shaft furnace in the Cordilleras should not overlook this point. The crucible and the jackets where the loss is the greatest should receive their special attention.

2. The direct use of fuel inside the furnace is the readiest and easiest way to increase temperature, but in copper matting, every pound of carbonaceous fuel inside the furnace tends to make poor matte; and poor matte is nothing but a reduction of the output of the furnace.

3. The use of hot blast. The well known properties of hot blast make it unnecessary to point out the advantages of its use at high altitudes where the heat losses are so great.

4. The use of back pressure on the furnace, in such a way that the fuel is forced to be burned at the pressure desired for its most economical working.

The combination of all these conditions favorable to high temperature in a single and easily worked furnace would be the ideal for high altitudes.

Two important Broken Hill mines produced the following in May:

	Proprietary.	South.
Ore milled, tons	27,960
Lead concentrate, tons	4,548
Lead content, per cent.	68.7
Zinc content, per cent.	6.9
Silver, ounces	22.3
Zinc concentrate	7,115
Zinc content, tons	3,281
Lead content, tons	529
Silver, ounces	91,540
Silver from mine and purchased ore,		
ounces	354,340
Lead, tons	6,667

The production of pyrite in the United States in 1912 was 350,928 long tons, valued at \$1,334,259. This is an increase in quantity of 49,470 tons, and in value of \$169,388, compared with the production in 1911, which was 301,458 tons, valued at \$1,164,871, according to the U. S. Geological Survey.

Metal production of the Mt. Lyell mines, Tasmania, during the period ended April 16, was as follows: Ore and fluxes smelted, 14,617 tons; blister copper content, 162 tons; gold, 414 oz.; and silver, 17,770 oz. The tonnage from the North mine is now increasing rapidly.

The Precipitation of Gold by Manganous Salts

By A. D. BROKAW

*Some interesting occurrences of gold associated with manganese dioxide led to the suspicion that manganous salts, under certain conditions, might react with solutions of gold salts to bring about mutual precipitation: the gold in the free state and the manganese as hydrated manganese dioxide. A search for literature on such reactions was without avail, and experiments were undertaken with a view to ascertaining if such reaction is possible, and, if so, under what conditions it can take place. The reaction in question is in a sense the reverse of the series of reactions involved in the well known 'chlorination process' of extracting gold from its ores:

and

The reaction is doubtless much more complex than the summary equations, but it will be seen that a reversal of the series would lead to the formation of gold and manganese dioxide.

Gold-Chloride Solution

Auric chloride solutions of varying concentrations were mixed with solutions of manganous chloride with concentrations ranging from 0.5/N up to saturation, but no reaction was detected even when the mixture was boiled for several minutes. The addition of a small amount of alkali to the mixtures, in the cold, caused an immediate precipitation of a dark brown mass resembling manganese dioxide in the hydrated form commonly precipitated. The precipitate was collected, carefully washed to free it from the gold solution, and then treated with standard oxalic acid, containing a small amount of sulphuric acid. The solution thus obtained was divided into equal portions: one was analyzed for manganese and the other titrated for loss of oxalic acid. The results showed that for every equivalent of manganese an equivalent of oxygen had been taken up by the oxalic acid, proving the precipitate to be manganese dioxide. In a check experiment the precipitate was taken into solution with the standard oxalic-sulphuric acid mixture, which was titrated for loss of acid. The manganese in solution was then reprecipitated as hydrated manganese dioxide by a standard method, and the precipitate was again treated with the standard acid mixture. The same loss of acid as before showed the original precipitate to be manganese dioxide.

Gold was left by the solution of oxalic acid and was readily recognized as such.

Gold chloride solutions are notably acid in their reaction, due probably to hydrolysis in part, and in part to the ionization of an addition product with water. Hittorf and Salkowsky showed by electro-

*Paper presented at the Milwaukee meeting of the American Chemical Society.

lytic experiments that gold chloride solution is ionized as follows:

Solutions of gold chloride show marked acid properties toward indicators, and apparently the acidity thus developed is sufficient to suppress the reaction,

If one postulates the intermediate formation of MnCl_4 in minimal amounts, he is justified in assuming that the salt would be largely hydrolyzed, since tetravalent manganese is a very weak base. This hydrolysis would be suppressed by the presence of acids, but on reducing the acidity, hydrolysis might become effective, forming the very slightly soluble hydrated manganese dioxide, and with this removed from the equilibrium system by precipitation, the reaction might proceed until concentrations were diminished to equilibrium conditions.

It is of interest to note that the precipitation began long before the solutions were entirely neutralized as shown by indicator tests. This was shown in another way by placing a crystal of Iceland spar in the mixture of gold and manganous chlorides in solution. A slight effervescence occurred, and after a few hours the crystal was covered with a brown coat of manganese dioxide in which flakes of gold were plainly visible. The precipitation of gold was practically complete when an excess of MnCl_2 was employed, though this solution had at least the acidity of saturated carbonic acid.

An interesting reaction of similar nature was found to take place between auric chloride solution and manganous carbonate. The precipitated carbonate (doubtless amorphous, in part, at least) reacts at once and is turned to the dark brown hydrated dioxide. The crystallized carbonate, that is, the mineral rhodochrosite, reacts slowly, but, after a day, a crystal was coated with dark brown and flakes of gold were plainly discernible.

Summary

If we suppose manganese tetrachloride to be an intermediate product, present only in very minute traces, we may find in it some basis of explanation. Suppose

Since tetravalent manganese is an exceedingly weak base it should be little ionized, but it may be subject to two other sorts of dissociation, namely:

1. A molecular dissociation,

2. Hydrolytic dissociation,

Theoretically we should have the hydrolysis constant

$$\frac{\text{Mn}(\text{OH})_4 \times 4\text{HCl}}{\text{MnCl}_4} = K$$

assuming hydrolysis according to the above equation. It is obvious that the presence of acid would tend to cut down the hydrolysis and allow the tetrachloride to become sufficiently concentrated to make its molecular dissociation appreciable—the greater

the concentration of acid the greater this tendency—and we may, in this way, easily obtain conditions under which free chlorine is liberated, as in the chlorination process.

If, however, the acid concentration is reduced below a certain figure the concentration of the tetrachloride will reach saturation. Any further reduction of acidity must result in the precipitation of the hydrated dioxide. It will be seen that such an adjustment may be very delicate indeed—and this seems to be supported by the lack of success in preparing the tetrachloride, subject, as it would be, to both hydrolytic and molecular dissociation.

An Automobile Hoist

The picture presented here was taken at the Banner mine near Randsburg, and shows a small automobile being used for hoisting purposes. A 600-lb. bucket is being used and is easily raised by this new type of hoisting machinery. As the shaft is deepened the road is lengthened and so the work

AUTOMOBILE HOIST.

goes on. From the work which has been accomplished to date by this new three speed forward and one reverse, direct-drive hoisting machine, the owners are planning to sink to a depth of 500 ft. When the hoist is not in use, it is a great convenience for hauling supplies and water and for bringing the miners to and from the property.

The Low gas-engine consists of a producer gas-engine with a compact producer attached to the end of the cylinder. Coal is fed into a hopper, from which it is conveyed by four screws through heater tubes. These pass through a gas chamber, connected with the engine inlet valve, the exhaust-heated chamber, the combustion chamber, and open into an ash and soot chamber. The latter admits air or steam to the tubes, which is drawn over the fuel by the engine suction. Tar has given no trouble. A 100-hp. unit only consumes $\frac{1}{2}$ lb. of coal per brake horse-power hour.

Fume from the Sumitomo copper smelter, at Yotsuzakajima, Ehime Prefecture, Japan, is still giving trouble, and the residents of nearby villages have asked that the payment of damages be continued. Compensation up to the end of 1910 was \$170,000, after which it was agreed to pay \$38,500 annually to the end of 1913. Hence the renewed agitation for further payments.

The Amakie Sapphire Fields of Queensland

By LIONEL C. BALL

*This district covers an area of 30 square miles. There is room for far-reaching economy in the breaking down and rough concentration of the wash, but no inducements are offered men of large ideas and resources, it being tacitly understood that the field is reserved for the small claim-holders. The employment of labor under such circumstances is at a minimum, as only the claim-holders in the richest ground can afford to pay miners the ruling wage of \$14.40 per week of 44 hours.

The digging consists in: (1) surfacing, or simply

MAP OF QUEENSLAND.

removing and treating the soil; (2) deep surfacing, which necessitates removing several feet of overburden that may or may not carry gem stones; and (3) sinking shafts through the overburden into the wash, the boulders and large pebbles of which are packed behind to prevent caving and to save unnecessary haulage.

As mapped by Mr. Dunstan, government geologist, who has exhaustively dealt with this field, there are five main 'runs' of wash. The following notes will show the character of the workings: At the Black Soil claim, 'wash' is found in the valley bottom. At Elwood's Grave, 13 men are hand-raking and sieving the surface soil. In one part of the area 'deep surfacing' is the practice, a 3-ft. overburden being removed to expose 18 in. of wash on bedrock. Some men average \$5 per day. At Grave Hill, the wash is 8 to 13 ft. below the surface, and 2 to 3 ft. is mined as 'pay.' One man can 'tub' three-quarters

of a load (say 3000 lb.) per week, yielding 0.5 to 3 oz. of first 'blues.' Some large stones, including a 16½ and 28-dwt. 'blue', were recently obtained west of this place. Iguana Flat is noted for the large size of its fancy stones. The Little Bessie wash is notably ferruginous, quite distinct from others being worked here. The successful treatment of the 'sands' in Retreat Creek has led to activity here, and several men make from \$3 to \$3.50 per day. A second bed of wash was proved at Ruby Vale, and on one claim 1 to 4 ft. of wash is being mined at a depth of 27 ft., yielding 0.5 oz. 'blues,' 0.5 oz. 'machine,' and 2.5 to 3 oz. corundum per load, with a few 'fancy' stones. The Queenslander claim has produced \$43,000 of gems in three years. The wash is 5 ft. thick and has yielded 4 oz. 'blues' per 'load.' On the Reward claims, the richest of them all, wash occurs on a low ridge, the deepest stripping being only 5 to 6 ft. The best gems come from near the surface, but the large dark violet stones mostly come from the deeper ground. Some are up to 3 oz. weight, and worn crystals of corundum up to 1½ in. diam. and 5 to 6 oz. weight are found.

Treatment of the Wash

Where, as on the Reward claim, practically all the gemstones are of large size, mechanical treatment of the wash is obviated by what is known as hand-raking, which consists in passing all the material broken down under the hand and examining it in the dry before throwing it back among the headings. Radical improvements have been introduced of late years, especially adaptation of South African diamond and corundum washing practices. The finer and lighter material is now treated in rotary machines. These consist of a circular iron pan, 5 ft. diam. and 12 in. deep, with circumferential feed and central discharge. The thoroughly moistened wash, as fed in, is stirred up by blades, each 10 in. long and 2 in. wide, attached to four arms driven from a central shaft making 7 r.p.m. The blades are set diagonally, with the object of throwing back toward the wall of the pan all heavy material including the gemstones, while the slush is allowed to escape through a central trap, passing thence by way of a launder to waste. It is stated that an essential for the successful working of the machine is that the wash during the pan treatment be in the form of a thick 'slurry,' to which clear water must on no account be added; but this is diametrically opposed to the ordinary laws of concentration. The capacity of Bradford's machine is estimated at 25 loads per day, but there is seldom more than 10 loads available at a time. The concentration, of course, varies with the nature of the wash, but usually a load is reduced to three or four sieves of gravel; that is, in the ratio of something like 50 to 1. Neither is the time required a constant, but a load of ordinary wash can be put through by three men in a quarter of an hour. The owners make a composite charge of \$1 per hour for carting the wash from the mine, if within a radius of two miles, and for putting it through the machine, in which, however, the claim-holders undertake the greater part of the labor of puddling.

*Abstract from *Queensland Mining Journal*.

and the whole of that of sieving the 'concentrate.' The heavy material saved is then roughly classified by hand in an ordinary circular sieve, with 1/5 to 1/10-in. mesh and a small removable perforated hopper having 1/2-in. holes. The 'hopperings' are thrown aside and the 'fines' neglected, but the gemstones in the middlings are concentrated on the bottom of the sieve by subjecting it under water to peculiar vertical and side shakes. It then remains only to invert the sieve on the ground and to pick out the sapphires from the other pebbles on the surface of the truncated cone of gravel so formed.

During 1912 the total production was valued at \$192,000. The demand for the gems is regulated by the lapidaries of Germany, who sell the cut material throughout Russia. The German firms have agents on the gemfields. In examination of a stone, the sky must be cloudless, for deep violet blues appear quite opaque in dull weather. Prices are as follows: fancy stones, \$1.25 to \$24 per dwt.; largest blues, \$28.80 per oz.; large blues, \$12 to \$16.80 per oz.; parcel blues, \$8.40 per oz.; small blues, \$1.80 per oz.; machine stones, 75 to 87c. per oz.; corundum (over 1 oz.), \$1.50 to \$2 per oz.; corundum (under 1 oz.), zircon, and spinel, unsalable.

A New Ore Gate

By GRANT H. TOD

At the Perseverance mine, Juneau, Alaska, H. J. Jackson, the superintendent, has recently devised a new gate which shuts off the run of ore from the

ORE GATE IN OPERATION.

chute to cars from the bottom upward. This allows the operator to stand above the chute line all the time, saving many accidents. The ore gate is counterbalanced and works with ease. The accompanying cut shows the chute, cars, and electric locomotive.

According to an English contemporary, the first round in the legal fight between the Golden Horse-Shoe and the London & Hamburg Gold Recovery Co. over the bromo-cyanide process, has been indecisive. A cable announces that judgment has been given in favor of the Horse-Shoe on the question of the Sulman and Teed patent, but against them on the Goepner and Witter patent. It seems likely that there will be an appeal.

Coke output of Indiana in 1912 was 2,616,339 tons, valued at \$12,528,685.

Mining Methods at Broken Hill

*A series of papers on this subject at the meeting of the Australasian Institute of Mining Engineers held at this centre in May, was preceded by a valuable general statement of the peculiarities in the mode of occurrence of the orebodies which resulted in the adoption of the various methods afterward described. Of these peculiarities, the most important are:

1. The shape of the orebodies, which are stated to be irregular in shape, of tremendous width in parts, and enclosed within poor walls. Developments at depth indicate that the lodes will be narrower and more regular, but it is a strange fact that even in the deeper levels the walls are often weak.

2. The physical properties (texture, etc.) of the ores, which vary from dense strong sulphides to porous friable sulphides and loose soft carbonates. In addition to the natural variations in texture is that induced by the crushing of blocks of ore as a result of previous mining operations.

The evolution of the methods characteristic of the field as a whole is put clearly by the authors as follows:

The first method of stoping employed was on the open principle, involving the use of 'clap-me-down' sets of local eucalyptus timber. This was found unsuitable, on account of the weakness of the ore, the walls, and the size of the deposits.

Then came the Deidesheimer square-set from Comstock, and with it a number of United States engineers to supervise its use. It was employed in overhand stoping, was used in horizontal floors, and was reinforced with angle bracing and bevel pieces, features of the original design. But so long as the timber was relied upon as the only support for the depleted ground, the stopes continued to fall in. Then came the winzing system, and the filling of the sets with waste quarried at surface. That modification made the square-set method a success, and enabled many thousands of tons of friable ore to be extracted. The square-set system is still being used extensively, and is not likely to be displaced for opening crushed and broken ground, although, on account of the greater attention being paid nowadays to filling, the angle-bracing is rarely seen in its completeness. An important change, however, in the manner of using the sets has been made on the field. In the picking-up of bottoms, in crushed workings, and in the mining of old pillars, the sets are now used in conjunction with underhand stoping. In this system of mining, the trouble with a weak back is minimized, the work rendered more safe, and the cost per ton reduced.

With increase in depth the ore changed from the oxidized to the sulphide minerals, which at shallow levels were in the friable condition, but at greater depths were hard and compact. The alteration to sulphides meant a lower-grade ore and a concentrating charge. Still, under the disadvantages of metallurgical difficulties and unfavorable metal market, the friable stopes showed profit on square-set work;

*Abstract from *Australian Mining Standard*.

but when the hard ground was properly entered, it was noticed that, in addition to the sets being too expensive, they were also unsuitable. Then came the introduction of the open stope proper, embracing the use of timbered gangways on the sill floor only, filling of depleted ground with waste, and the utilization of 'pig-sties' or cribs in the working place. And, although many changes have been made in detail, the same system, in principle, prevails to a considerable extent today.

Individual Companies

The special characteristics of the underground operations of individual companies are described as follows:

South Blocks.—This at present is working a narrow orebody, practically vertical, and having only one wall. The conditions are such that rill stoping, combined with filling from continuous passes, skip haulage, and fathomage contracts, is possible, and is successfully accomplished.

South Mine.—This is operating open stopes in large, irregularly shaped shoots on the 970 and 1070-ft. levels; and above are picking up bottoms, and working away old pillars, with heavy square-sets on a cross-cut system.

Central Mine.—This mine on the deepest levels is open stoping a new orebody east of the one previously worked; but higher up is mining with square-sets old workings and old pillars that have 'crept,' and are still slowly subsiding.

Block 10.—This mine is the deepest on the Barrier, and, as the lode is narrow at depth, the stoping operations are on an open-rill system. There are many problems here, though similar to the Central mine, the 'creep' having affected both properties, and they are dealt with in a similar manner by square-setting. This work is going on under old workings, on both an underhand and flat-floor system.

Proprietary Mines.—This mine is also open stoping at the deepest levels, but upward its problems are, perhaps, more varied than those of any other company. The square-set method predominates, and is employed in all classes of ground, including hard ore in deep levels, crushed ore in 'crept' stopes and 'bridges,' and loose running material partly oxidized underneath the open cut and in proximity to an old fire.

Block 14 Mine.—This company is engaged in the recovery of carbonate ore from old stopes on shallow levels with the aid of square-sets, and in the stoping of compact sulphides at depth in open workings.

British Mine.—This is distinctly an open-stope mine, mainly on account of the hardness and strength of the ore. Both the lower portions of a lift, and the bottoms as well, are worked on the bulk system, booms, of course, being freely used for the last slice. Only in the case of friable ore are square-sets called into requisition.

Junction Mine.—This is re-working old stopes left unfinished, and re-entering others that had 'crept,' with the aid of square-set timber. On the deeper levels the strength of the ground warrants the use of the filling and bulk system.

Junction North Mine.—Here, again, the strong na-

ture of the ground allows of the employment of open stopes until the lower levels are approached, when a change is made to set timber. At present the 1200-ft. level is open; but above it, bottoms are being secured on the usual system.

North Mine.—This mine has two ore-shoots having good walls and pitching with remarkable uniformity downward in a northeasterly direction. The strength of the ground allows of open stoping, and the regularity of the deposit generally makes possible a standard system of drifts, cross-cuts, and winzes, and the installation of an efficient and cheap method of handling filling.

Utilizing Sulphuric Acid Cinder

Nearly \$18,000,000 worth of sulphuric acid is made yearly in the United States, being used in the manufacture of superphosphates, explosives, in refining crude oil, and in a great variety of chemical industries. Much of this is made from pyrite, which is treated in roasters to liberate the SO_2 , which is then made into sulphuric acid. The calcined residue, still containing about 2% sulphur, sometimes contains enough copper to make its extraction, by leaching or otherwise, profitable. Except for its sulphur content and fine state of division, the calcined residue resembles a good grade of iron ore, and a good deal of effort has been devoted to utilizing this residue in iron smelting, especially since it is commonly low in phosphorus. By nodulizing the calcine in kilns the residue can be brought to a low sulphur content and at the same time so agglomerated as to make it a desirable addition to the iron blast-furnace. In the case of residues which contain about 1% of copper, this is first extracted by leaching, after which the cinder is nodulized. If the copper is less than $\frac{1}{2}$ to $\frac{3}{4}$ %, its extraction is not profitable. The cost of nodulizing is also so nearly equal to the value of the resulting product that this operation is not very profitable. At the plant of the Pyrites Co., Ltd., which is engaged in the manufacture of sulphuric acid from Rio Tinto pyrite, there has just been put into operation a 150-ton Dwight-Lloyd sintering machine for sintering the cinder. About 8% of coke-dust is mixed with the cinder; the cost of the operation is considerably less than in nodulizing in kilns, the sulphur being reduced from 2 to 0.04%. There is a tendency at present to use copper-bearing steel for rails for railway service, and if the use of steel containing copper should increase, it is not at all improbable that the burning of copper-bearing pyrite for the manufacture of sulphuric acid, nodulizing the residue, and smelting in the blast-furnace to yield a copper-bearing pig iron will become an important phase of future practice.

Asphalt and bituminous rock production in the United States was 449,510 short tons, valued at \$4,620,731 in 1912. That of Trinidad was 189,496 tons, and Venezuela 65,875 tons.

Mt. Morgan, Queensland, in May returned the following: Ore smelted, 21,911 tons; blister copper, 662 tons; and gold, 9169 oz., valued at \$374,000.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Dewatering Tank

The Editor:

Sir—In your issue dated June 21, 1913, C. F. Spaulding has an article on 'Continuous Agitation with Barren Cyanide Solution,' in which he gives a drawing showing 'Young's Dewatering Vat.' Upon

DEWATERING PLANT USED BY THE WAIHI GOLD MINING CO.

reading this article one would conclude that this idea for dewatering slime was something new. I would like to state that the Waihi Gold Mining Co., Ltd., of New Zealand, completed a plant in 1908, on these identical lines, for dewatering about 700 tons of slime per day. The plant works well, and gives a thick discharge of slime, at an extremely low cost.

The plant consists of four conical bottomed tanks, each 17 ft. square and the cones of each pair of tanks, are connected up to a disintegrator. The de-

watered slime is churned up with weak cyanide solution in the disintegrator, and from there it is elevated to agitators. Each tank contains 15 Moore filter leaves; each leaf being 16 ft. long and 4 ft. 6 in. deep. The total filtering area in the four tanks is about 9000 sq. ft. The dewatering operation is simply a matter of collecting and discharging cakes. Care has to be exercised in regulating the outflow of the thickened slime, otherwise the thin slime, in the upper part of the tanks, may break through into the disintegrator.

CHARLES A. BANKS.

Greenwood, British Columbia, June 28.

Lead Salts in Cyanidation

The Editor:

Sir—The following example of the effect of lead salts on the extractions by cyanide of the gold and silver in an ore which I was testing recently, may be of interest. The ore, assaying about \$7 Au and 5 oz. Ag, consisted of a mixture of clean oxidized quartz and vein material (mostly calcite), the last carrying some of the metal. An analysis of the ore revealed no constituents prejudicial to treatment by direct cyanidation, except the presence of traces of manganese, which might possibly retard the dissolution of the silver. Agitation with solution produced a 95% extraction of the gold in 20 hours, but after 60 hours, even with solution titrating as high as 0.25% KCN, the silver extraction reached only 58%. The addition of lead acetate (0.5 lb. per ton of ore) at the start of the agitation caused the gold extraction to drop to 65%, and that of the silver to rise in 24 hours to 75%. By agitating for 20 hours and then adding the lead acetate and continuing the agitation in the same solution for a further 24 hours, the gold extraction reached 96% and the silver 89%. No appreciable increase in extraction of either the gold or silver was obtained by decanting the solution after the 20 hours and replacing it with fresh solution, before adding the lead acetate. Finely ground litharge had exactly the same effect as the lead acetate. The tests were conducted with precipitated solution from a plant where lead acetate, at the rate of 0.6 lb. per ton of ore, is added to the solutions.

VYVYAN C. BENNETT.

El Oro, Mexico, May 26.

The Franklin Furnace zinc mines, in New Jersey, continue their large output of zinc ore, producing an increased tonnage for 1912. The concentrating mills treated 363,588 short tons of crude ore, producing 298,901 short tons of concentrate. In addition, 95,997 short tons of crude ore was shipped. The total crude tonnage sold or treated was therefore 459,585 short tons, against 374,064 tons in 1911. The total recoverable zinc output in 1912 (figured as spelter), was 139,510,008 lb., against 154,890,900 lb. in 1911.

Diamond production of German Southwest Africa is growing. Shipments in June are estimated at 170,000 carats, one property yielding an average of 50,000 carats per month.

Special Correspondence

DENVER, COLORADO

COLORADO LOOKING FOR MINES.—PLATORO.—BIG PRODUCTION AT CRIPPLE CREEK.—NEW MILL AT IDAHO SPRINGS.—PITCHBLLENDE IN GILPIN COUNTY.—EAGLE AND THE NEW SILVER MINE.—HOPES IN THE NORTHWEST.

Public interest in mining is low at present in Colorado, and the business is suffering its full share of the general depression that is being felt. It is true that it is not in so bad a way as that of real estate, which, as one ex-dealer expressed it, has "died a natural death," and yet it is hard to stimulate much local interest in mines and mining. So true is this that the somewhat forced publicity that Denver papers have given Platoro and Eagle has but served to create a prejudice against those two promising districts. Platoro is an old district, not far from Creede, that is being revived as a result of discoveries made last fall and described in the *Mining and Scientific Press* months ago. It is too soon to give a final answer to the question as to the value of the district. The first hopes of abundant high-grade ore have yielded disappointment, but that there is a considerable tonnage of ore of a grade now workable in other districts of Colorado, seems demonstrated. Whether it will pay to build the transportation lines and other utilities necessary to market it, is still uncertain; but the matter is being studied by men of experience, and it is at least hopeful. Cripple Creek is now a great low-grade camp, and is turning out a tonnage that is impressive. It is to be remembered that, in the main, the money made in Colorado mines has come from relatively high-grade ores, and the work done by Philip Argall at Stratton's Independence, G. M. Taylor, Thomas Crowe, and their associates at the Portland, and the active staff of the Golden Cycle, has demonstrated that, right in Colorado, in known districts, much money is to be made by proper efforts. There is no reason why a profitable low-grade mine must be as far away as Alaska or even the Black Hills. This new mining may be less dramatic, but to the state as a whole is likely to be profitable as gouging rich streaks. If local capital is not ready for the task, foreign money apparently is, as has been shown by the success of A. L. Burris in making a market in Europe for El Paso stock. His later and larger consolidation of Cripple Creek properties is being watched with great interest and much hopefulness.

In the meantime, other old districts jog along at about the same rate. At Buena Vista, George Collins has the Mary Murphy producing at a satisfactory rate, and seems to have tamed, at least temporarily, the wild Irish lady who has been the cause of much anxiety and grief. Perhaps Mary's days are numbered, but at least she is giving an edifying exhibition of a dignified old age. At Idaho Springs there is, as usual, a new mill. This is the long-promised one at the mouth of the 'Newhouse tunnel,' built by a subsidiary of the Argo company. It is in charge of A. H. Roller and is run on a custom basis, buying ore from the various mines operated in the tunnel. It is interesting as an application of cyanidation to ores long treated by amalgamation and concentration. Crushing is in solution with stamps. This is followed by concentration, fine grinding in tube-mills, and agitation. The mill is said to be giving excellent results, though detailed records have not been made public. Granted that it makes a good recovery, as is entirely probable, there is still a question whether it is not a forced attempt to get away from smelting rather than a real development in the technical practice of the district. Since the North American smelter at Golden closed, the Globe affords the only market for Clear Creek and Gilpin county ores. With only two furnaces running, it would not seem that the output was large enough to warrant much division of field—if only there was a better understanding between the miners and the smelting company. The conflict of interest cuts deep in Colorado, however, and it is doubtless too soon to expect complete harmony.

Gilpin county, while not deserting gold mining, is developing an interest in other minerals. The pitchblende is found in the German and Belcher mines, and described by Forbes Rickard in the *Mining and Scientific Press* of June 7, is attracting serious attention from medical men. Dr. H. E. Kelley, of Johns Hopkins Institute, has recently visited the property. It is known that no new sources of supply are being found in Austria, and that, in fact, the radium that comes from that country is derived from accumulated residues. Carnotite, while used as a source of radium, is proving a trifle disappointing. The refinery at Pittsburgh has not, as yet, succeeded in keeping up the grade to the expected figure, and altogether the pitchblende of Gilpin county seems likely to prove of large humanitarian value, whatever may be the financial outcome. It is understood that the enterprise is being financed by an Eastern man without hopes of return, but as a measure of scientific and humanitarian interest. This gentleman, who prefers to remain unknown, is, by the way, one of the 'trust

MAP OF COLORADO.

magnates' whose company is in the public press. The company concerned has added the Wood and another property to its holdings, and is steadily piling up ore. If a sufficient amount to justify the venture be found, a refinery will be built at Denver or some suitable point. Mr. Rickard is managing the property.

Eagle continues to receive much notice in the local papers, and while the actual amount of ore so far found is not large, it is by no means certain that the district does not deserve the attention given it. The significance lies in the fact that silver ore of good workable grade occurs in the midst of a country so far devoted to ranching, and in a situation easily and long overlooked. It raises the natural question of how many similar bodies of ore are still to be found, not only in that vicinity, but in others in which the same conditions obtain. The geology of the district has already been noted in the *Mining and Scientific Press*. Briefly, the silver occurs as a replacement in a certain favorable bed of mesozoic sandstone, at the intersection of this bed by fissures, that are not especially conspicuous, and which do not mark faulting, though there are faults near by. In the sandstone are specks of copper carbonate, both malachite and azurite, and on its surface are small blotches of a lemon yellow mineral resembling the common alteration product of carnotite. The silver is in part in the form of chloride, and in part possibly that of argentite. It occurs not on 'facings' of the rock, but in the mass, and on freshly broken pieces may be seen as silver gray specks. Individual specimens assay as high as 3000 oz. per ton. The outcrop assayed 18 oz. and carload shipments assay 100 to 120 oz. There is only a trace of gold, and no noticeable lead, zinc, or pyrite.

So far, 19 cars have been shipped. The ore goes direct to the smelters at Leadville and Salida. Along the main fissure, mining has continued about 90 ft. A cross-cut to the east shows other fissures, and stopping, both up and down and along the dip of the favorable bed, shows groups of parallel fissures that contain ore. In the workings of the Lady Belle Syndicate lease, the only one shipping, the sandstone bed in which the ore occurs is five to six feet thick and dips about 15° at right angles to the strike of the fissures. The mineralization has extended from fissure to fissure, so that the whole body is workable from the outcrop down the dip 50 or 60 ft. Not all the fissures, of which there are three prominent groups, have been followed along the strike, and the main group still showed eight inches of high-grade ore in the face when visited. The favorable bed of sandstone is dark, earthy in appearance, and seemingly contains organic matter or ferrous iron compounds, or both, either of which may well have acted as a precipitant for the mineral of the invading solutions. It forms one of a series of beds of ordinary-looking Mesozoic sandstone. The talus in the vicinity shows fragments of a fine-grained dark igneous rock, and dikes are reported to occur in the district, though none have been found in or near the workings.

The Lady Belle mine was discovered last fall by prospectors who originally had been looking for copper, and who were grubstaked by a rancher and the postmaster, E. E. Glenn. In February, the value of the ore became generally known, and there was a rush into the district with a lot of staking of claims on the snow. There are now about 75 people in the camp, which is eight miles south of Eagle, and the number includes several experienced prospectors. There is a large territory, which, to superficial examination at least, offers hope of the finding of ore, and there would seem to be good prospects of the finding of additional orebodies. In the meantime, the Lady Belle should make money for its owners, as no mill and only the simplest equipment is needed. It has by no means been demonstrated that 'another Aspen' has been found, but the district is worth watching.

Northwestern Colorado remains a luring land of mystery, and despite repeated disappointments, there are many who retain hopes of finding there another big district. The region is now being studied by an experienced and successful engineer, who has had enough faith to grubstake a prospector for some months. Ore assaying \$70 has been found, and the engineer is now in the district verifying the reports of his prospector and attempting to learn how much of such ore is present. It is greatly to be hoped that the venture proves successful; but at any rate, it is evident that the day of the prospector in Colorado is not yet done. Mining has naturally centred on the outcropping bodies of easily recognized ore, but sharper eyes and more trenching may at any time open bonanzas as rich as any yet found.

MELBOURNE, AUSTRALIA

TRoublesome Miners.—A CASE OF SALTING.—TASMANIAN MINING DEVELOPMENTS.—DREDGING IN VICTORIA.

The miners of the Commonwealth seem to be bent on rendering it impossible for the mine-owner to carry on operations profitably. In Queensland, one of the principal fields, Cloncurry, is practically at a standstill because the union has decided that work is to be paid for at so much per day, instead of by results or by contract. Those who have had much to do with the local workman know the outcome of substituting day labor for contract labor or for piece work—it means, in two words, less work. In Victoria, on the Bendigo field, a strike is threatened unless the mine-owners refuse to employ non-union labor. This was the demand made by the Broken Hill, New South Wales strikers, recently, which, as may be remembered, failed. Undaunted by this example, the Bendigo men are pushing along to the same end. The employers have given them clearly to understand that they do not mean to give in on this matter; but it is difficult to say what the end will be. So far, the threatened strike has not

taken place, and if the men have any wisdom it will not eventuate.

J. E. Carne, of the New South Wales Geological Survey, has issued a remarkable report on a recent alleged discovery of mineral oil at Diamond Head, in the northern part of the state. He has not minced matters, but says plainly that 'salting' (should we not say 'oiling'?) has been resorted to. The first announcement or 'find' had reference to the presence of oil floating in the water of a creek, and to seepage from the banks. Afterward, two small drill-holes were put down in the black sand rock sloping down the creek, the deeper of them being 7½ ft. In this, at the time of Mr. Carne's examination, there was about 5 ft. of water, and in the sand and mud of the drill-hole, were seen small globules of crude or residual oil. A drill-hole was put down 8 ft., within 4 ft. of this oil-showing hole, and yielded nothing at all, though, if the occurrence had not been faked, the water seepage would have shown traces of oil. Mention is also made of the fact that the first sample taken to the Mines Department consisted of sand saturated with refined kerosene—"Nuff said."

Tasmania has been excited more or less by a discovery of osmiridium, and a company has been floated in Melbourne, Victoria. There have been two or three good discoveries, all in the Waratah district, but the people who expect great things as a result, are probably doomed to disappointment, as the *Australian Mining Standard* says not much need be expected of an industrial metal that is mined in ounces. It is claimed, by the way, that one of the nuggets unearthed by one of the successful prospectors weighs 2 oz., and that it is considered the largest specimen in the world. In one case, the alluvial, in which the metal occurs, has been traced to a large iron outcrop, and it is believed by the prospector that this is the source. Some interest is also being taken in a new nickel-copper field in the Zeehan district, which is being examined by two of the Broken Hill (New South Wales) companies. The result of their operations has not been made public, but from what can be heard it has not been entirely satisfactory.

Tasmania has yet another chance of achieving fame in the production of a mineral of which that island has not yet produced any great quantities, the state's assistant government geologist, Mr. Hills, having reported that the Prevlenna field contains 5,000,000 tons of coal of excellent quality available for mining. He recommends the construction of a tramway for getting to the railway the coal and timber, of which there is a considerable quantity. Much satisfaction is felt from the fact that the independent report upon the disaster at the North Mt. Lyell mines, last year, when 43 men lost their lives, has resulted in the complete exoneration of the Mt. Lyell company. The examination was made by Alexander Montgomery, the state mining engineer of Western Australia, at the request of the Tasmanian government. He finds that the disaster was abnormal, and could not have been foreseen or prevented. Mr. Montgomery is of the opinion that, even if there had been a second exit from the mine, there might have been no less loss of life. As a result of the accident, the Mt. Lyell company lost \$182,000 on its operations during the six-month period, and the usual dividend was accordingly not paid.

The Victorian daily press has been making a great outcry about the great injury done to agricultural areas, pastoral areas, and scenic areas by what it sees fit to describe as 'the devastating dredge.' In consequence of its efforts, a commission has been appointed to inquire into the damage done by gold-dredging operations in the rivers of the state. The inquiry has shown that the industry has a much greater amount of public support than the Melbourne papers had supposed. At Bright, for instance, a town which was supposed to have suffered severely, a public meeting carried resolutions protesting against the unfair and biased statements that had been made, and declared that the stopping of the industry would cause heavy loss to the residents of the district. The report of the commission will be awaited with interest.

NEW YORK

COPPER MARKET.—THE MEXICAN SITUATION AND THE NATIONAL RAILWAYS OF MEXICO REPORT.—TONOPAH AND COBALT STOCKS.

Resumption of the buying of copper was a leading feature of the New York market during the week ended July 19. The nominal quotation for the metal continued shrinking until, on July 15, large purchases for export shipment were made on the basis of 14¼c., and the bookings during the remainder of the week are estimated at over 50,000,000 lb. The sales were so heavy on July 16 and 17 that producers advanced the price to 14¾c. and the week closed with it firm at that figure. Domestic buyers began to come into the market at the end of the week, and it may be expected that the price of copper will continue to advance for the time being at least. The European sales were for August-September delivery, but the domestic buying is for August delivery. Exports of copper for the first 17 days of July were approximately 34,500,000 lb., which is taken to indicate that the total for the month will reach 62,000,000 lb. The foreign statistics on July 15 showed a decrease in the European metal stocks for the first half of the month. Stocks in England, France, and afloat were given as 29,358 tons, an increase of 1186, but the stocks at Rotterdam, Hamburg, and Bremen decreased 2109 tons, to 7944. The London market is reported as strong, and sellers in the country predict that the price of copper will advance to 15c. within a few days.

The greatest topic of public interest has been the Mexican situation. Undoubtedly it is bad, everybody has known that for a long while, but there is some doubt as to whether recent developments have or have not been engineered in order to force the hand of the Wilson administration. H. L. Wilson, the ambassador, has been instructed to proceed to Washington for a conference with Mr. Bryan, who has unwillingly temporarily abandoned the Chautauqua platform for that purpose, and by the time this is in print some vigorous action may have been taken. There is in many quarters the feeling that, following the representations made by the European nations at Washington, the Wilson administration must either offer to let them take any action they desire in Mexico, or else intervene to secure order and protect foreign lives and property. The administration obviously planned to put the Mexican question in cold storage for the summer, but it seems to have melted all the ice. Just what happened is difficult to learn, but it is reported that Germany demanded protection for her citizens in Mexico and for their property, on the ground that the Monroe Doctrine precludes the intervention of Germany to secure their protection. It is stated that similar requests have been or will be made by other European powers. British investments in Mexico are estimated at \$320,000,000 in value, while French interests have \$140,000,000, and the United States over a billion dollars worth of property. E. N. Brown has definitely resigned as president of the National Railways of Mexico, stating that Governmental interference in the management of the railway made it impossible to attain success under present conditions. The gross earnings of the system for the year ended June 30 show a shrinkage of 10% as compared with the preceding year. The total net income is expected to be about \$22,400,000, which, after providing for fixed charges and reserve funds, will leave a deficit of \$214,000. Considering that nearly half the system has been shut down for over half of the year, the showing is not as bad as it might have been expected to be. It is expected that a number of other American officials will follow Mr. Brown's lead in resigning.

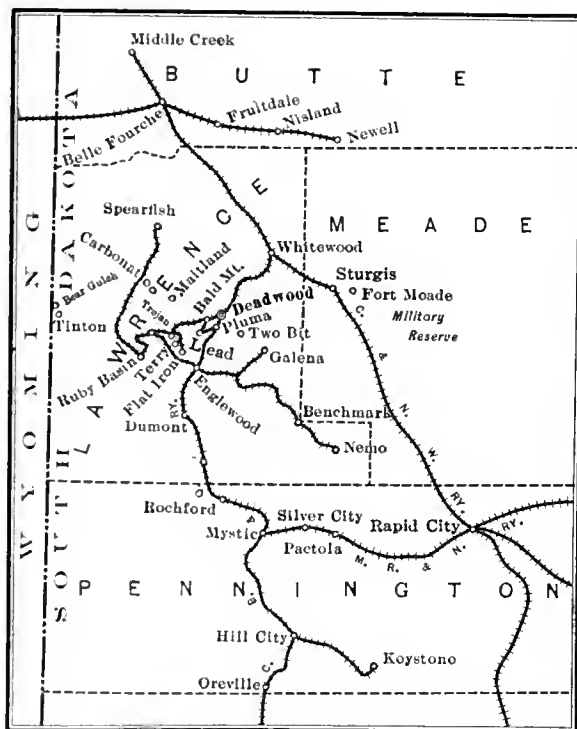

On the Curb market, Tonopah and Cobalt shares continue to be the focus of interest. By the aid of strenuous boosting Tonopah North Star has been advanced from 17c. to nearly \$1.10 per share, and a number of other minor Tonopah issues have profited by its advance. The most active Cobalt stock is Canadian Gold & Silver Mining, a property which is well situated and is said to exhibit promise in the development in progress. This property has the backing of Catlin & Powell, but Tonopah North Star enjoys no such evidence of respectability. Alaska Gold Mines is reported

to be about to depart from the Curb to the 'Big Board,' a change which it has already made in Boston. Alaska shares recently advanced to 18½ or, more accurately, declined, since the half-paid certificates sold at nearly the same quotation some time ago. The La Rose recently gave out its half-yearly report, which shows gross earnings of \$811,588, net earnings \$476,968, and dividends of \$396,010. During June 233,724 oz. of silver was produced. The Cobalt Lake has declared a dividend of 2½c. per share payable August 15. The Peterson Lake has declared its fourth dividend, payable on the same date, of 10c. per share. The Crown Reserve will also pay its regular monthly dividend of 5c. Speculation is rife as to what the dividend declaration of Buffalo Mines will be, and whether Temiskaming will pay a midsummer dividend following its meeting, July 26. June production at the McKinley-Darragh was 185,182 oz., which shows a decline from last year's rate.

DEADWOOD, SOUTH DAKOTA

VALUATION AND TAXATION OF BLACK HILLS MINES.—OPENING TITANIC AND ELLIPTIC MINES.—HOMESTAKE EQUIPMENT AND DIVIDENDS.—LEASING AT THE GOLDEN REWARD, MINERVA AND IRONSIDES.—WASP No. 2.

Taxation of mining properties has been a matter which has recently claimed the attention of Black Hills operators, since a decision was arrived at to place the valuation at a figure more nearly the actual worth. In the past, the rule in this section has been to make the valuation at a

BLACK HILLS MINING DISTRICT.

figure greatly below the actual worth, but a state tax commission, created by the last legislature, has ordered large increases. The assessed valuation of the Homestake, typical of Black Hills properties, has been increased three-fold, and many items not previously listed have been added. For instance, bullion on hand on July 1 was listed at \$125,000. Other properties have been increased in like proportion, and in some instances non-productive property has been valued at an almost exorbitant figure. It is promised that the tax levy will be reduced far below former figures, so that the gross taxes paid will be about the same as formerly; but, as is the case every time a radical change is made in a system of taxation, and an earnest effort is made to ascertain the true value of taxable property, much dissatisfaction is expressed.

Cleaning out the old single-compartment shaft, enlarging it to two compartments and timbering with substantial square sets, is going rapidly forward at the Titanic in the

Carbonate district. The old shaft is a little over 100 ft. deep, and is repaired and enlarged nearly to the bottom. In addition to sinking to the 300-ft. point, the company will cross-cut from each 100-ft. level. The work is being done on the Carbonate claim of the Iron Hill company, about 200 ft. west of and 50 ft. lower than the mouth of the Iron Hill shaft. From the latter shaft, during former operations, an immense quantity of ore was extracted. The work now being carried forward by the Titanic company is destined to explore a virgin territory along the main ore making fault of the camp. A commodious shaft-house has been erected, and arrangements made for the installation of a hoisting engine as soon as it is needed.

At the Elliptic property, men under the management of F. S. Stratton have unwatered the 700-ft. shaft and installed a diamond-drill at the bottom. Former drilling is stated to have exposed a body of remarkably rich free gold ore at a depth of 600 ft. below the shaft bottom. Mr. Stratton and associates are seeking confirmation of these results, and should they be able to open anything similar, will continue the shaft and develop the property thoroughly. A great deal of interest attaches to this work, as it is in a country outside of the recognized productive district, and success will mean the stimulation of prospecting over a wide territory.

The Hill City Mining & Development Co. is working energetically on its property in the Hill City district, and is securing results of a highly encouraging nature. The ore is largely free milling, and from present indications is of large extent. It is planned to erect a mill at an early date.

Differences among the stockholders have been adjusted and the following directors elected by the Cumberland company at Hill City: F. C. Crocker, president; Jackson Crocker, vice-president; J. W. Fowler, Jr., secretary-treasurer; Alex Madill and F. L. Livingston. The warring interests have had a long siege in the courts, but now that peace again reigns it is proposed to resume work. The property has in the past been a heavy producer, and is equipped with hoist, compressor and a small stamp-mill.

Twenty stamps have been added to the Homestake equipment, making a total of 1020 stamps now dropping at this great property. Production is up to the normal, and for the first half of the present year, from January to June inclusive, \$936,000 has been paid in dividends. The present monthly dividend, since the increase in capitalization, is \$163,254. In common with all securities on the New York exchange, Homestake has settled to a point where it is an attractive investment, and local parties are buying when they can get the stock around \$100 a share.

W. T. Boley is making an examination of the Republic property in Blacktail gulch, and will outline plans for future work. During last winter and spring considerable development was done, but operations were suspended in April. Officials of the company, residents of Chicago, are at the property. It is reported that Mr. Boley will have charge of work upon resumption. The property contains several good shoots of ore, and a mill is among the possibilities of the near future.

The leasing system is proving successful at the Golden Reward, where it has been followed for upwards of a year. There are at the present time 44 lessees at work at various points, and a large proportion of the mill supply is produced by them. Some of the leases are yielding smelting grades of ore as well, and the work is responsible for prosperity in the Bald mountain district almost equal to the boom days of the camp.

Peterson & Co., leasing on the Minerva in Blacktail gulch, are getting encouraging results, and are preparing for a mill run. The Esmerelda mill has been secured, and may be repaired for their use. The property is in the conglomerate belt, and the present tunnel is following a course destined to intercept, should it continue, a shoot that produced some fabulously rich ore some years ago.

Lessees at the Ironsides, in Squaw creek, are getting out high-grade smelting ore, and as soon as the wagon road to Maurice station, on the Burlington, is repaired, shipments will commence. The ore is the richest sylvanite ever

found in the Black Hills. The property laid idle for over 10 years. The present lessees have been working about three months. Their work is being confined to drifting and cross-cutting 15 ft. below extensive lateral workings opened by the former operators. This is an illustration of how easy it is in mining to miss a good thing by a narrow margin.

Owners of the Rattlesnake Jack mine, in the Galena district, have purchased the Saginaw mill at Custer, and will move it to the property and equip it with a cyanide department. The plant contains 20 stamps, and is practically new and up-to-date.

Wasp No. 2 continues to yield dividends, the disbursement made on July 14 being at the rate of one cent per share. A system of belt conveyors will be installed under the tanks for removing the tailing, thus doing away with hand tramping, and also reducing the time consumed in dumping.

BRITISH COLUMBIA.

RESULTS OF THE FIRST HALF OF 1913.—OPERATIONS OF MINES IN THE EAST AND WEST KOOTENAY, ROSSLAND, BOUNDARY, SIMILKAMEEN, AND COAST DISTRICTS DETAILED.

Metal mining in the East Kootenay district is still restricted almost altogether to the Sullivan group of mines, operated by the Consolidated Mining & Smelting Co., which has sent from here to its smelter at Trail, during six months to July 1, between 17,000 and 18,000 tons of lead ore. A few hundred tons have been sent from the same Company's St. Eugene mine, but there has been no other ore production in the main part of this district. Coal mining has continued generally active, and in the extreme southeastern part, in the Flathead country, drilling for oil is in progress.

In the Ainsworth division of West Kootenay the Bluebell has shipped to Trail about 4000 tons of lead concentrate this year, and No. 1, Silver Hoard, and Utica have been smaller shippers. Other operators were the Florence company, on Woodberry creek, and Retallack & Co. at White-water. In Slocan, the Lucky Jim has shipped zinc ore, while silver-lead has been sent out by the Rambler-Cariboo, Standard, and Van-Roi in considerable quantity, and by several others in much smaller lots. Work has been continued on the Payne, developing at depth, and the Ruth-Hope, Richmond-Eureka, and Slocan Star, all near Sandon, continue to be active, with the last mentioned now in good ore and making preparations for a resumption of shipping after a long period of non-productiveness. About Cody, the more important operations are those of the Noble Five company and on the Surprise. In the vicinity of Alamo, the Idaho-Alamo group is shaping well for resuming production, while mines tributary to Slocan lake, additional to the Standard and Van-Roi already mentioned, are the Hewitt-Lorna Doone group of the Silverton Mines, Ltd., the L. H. being developed by the British Columbia Copper Co., the Ottawa by the Consolidated company, and several others. About Nelson, the Queen Victoria is shipping to Greenwood, the Eureka and Silver King group are being developed, the Molly Gibson will soon be again sending out ore, and the Granite-Poorman soon be crushing gold ore. In Ymir camp, the Yankee Girl has shipped about 3000 tons of gold-silver ore during the half-year, while development at both the Wilcox and Dundee is reported to have opened good ore. About Salmo, the Emerald and H. B., both lead mines, have been shippers, and in Sheep Creek camp, the Queen in larger and the Motherlode in smaller quantity, have been mining gold ore. At Erie camp, the Arlington and Second Relief have also mined gold ore. In Lardeau district the Ajax and Silver Cup group have been worked this season, but there has been little production from other district properties. The only other mining camp in West Kootenay calling for mention is Rossland.

Aggregate figures from Rossland show an ore production of about 121,000 tons for the first half of 1913, in the following approximate proportions: Centre Star-War Eagle group, 72,000 tons; Le Roi, 29,000 tons; Le Roi No. 2, 10,800 tons first-grade shipped crude, and 9000 tons second-grade

concentrated; and small shippers, 200 tons. A small power-plant is being put in by the Richmond Consolidated Co. There is a general feeling of confident expectation, in the town, of long-continued and profitable production from local mines. Allowing for June an average of the five months ended May 31 in quantity of ore smelted at the Consolidated Mining & Smelting Co.'s works at Trail and gross value of metals contained in same, the figures for the half year are as follows: Approximate quantity of ore and concentrate smelted, 162,000 tons; gross value, \$4,232,000. The figures for the whole of the last fiscal year were: Ore and concentrate treated, 296,458 tons; gross value of metal contents, \$5,083,078. The monthly average for the expired part of the current year is higher by about 2300 tons of ore and nearly \$282,000 in value of metals. Additions to buildings and plant are being made at these smelting works.

The aggregate of production from Boundary mines during the six months has been about 910,000 tons of ore, smelted at

MINING DISTRICTS IN BRITISH COLUMBIA.

the Granby and British Columbia Copper Co.'s works. Of this total, 612,000 tons was from the Granby company's mines and 291,000 tons from those of the British Columbia Copper Co. The No. 7 mine shipped 3600 tons to Trail and the Jewel crushed about half that quantity at its own stamp-mill. The remainder was contributed by several small shippers. In addition, some 30,000 tons from United States mines was received at district smelting works. The British Columbia Copper Co. is preparing to concentrate ore from its Lone Star mine.

The Hedley Gold Mining Co.'s production at Similkameen for the first half of 1913 shows a proportionately nearly similar quantity of ore crushed in its 40-stamp mill to that of last year. The actual figures for five months, to June 1, are 29,180 tons crushed, yielding gold valued at \$377,483. The average monthly tonnage is, therefore, 5836 tons crushed, as compared with an average of 5872 tons per month throughout 1912. In recovered value, though, there has been an increase of between 15 and 16%, an average of \$12.94 per ton, as compared with \$11.19 last year. In his last annual report, to December 31, 1912, the Company's general superintendent stated that the minimum quantity of reserve ore, as shown by development and diamond-drill, was 413,000 tons, and that this ore will average at least \$11.35 per ton. It will be seen that the recovered value during five months of this year has been \$1.59 per ton higher than that general estimate. The New York Syndicate No. 2, comprising men largely interested in the Hedley company, is holding, under option of purchase, a group of mineral claims in the vicinity of the Nickel Plate group, and is prospecting these by diamond-drill, under the direc-

tion of T. Walter Beam, of Denver, Colorado. The British Columbia Copper Co. is continuing its exploration of several groups of claims on Copper mountain, 12 miles from Princeton, having five diamond-drills at work and doing underground development as well, with encouraging results thus far. Summit, which is the headwaters of Tulameen river, is attracting much attention, and there are some good showings of ore opened. This town has been called Leadville by a 'mining-on-paper' man, but is not officially recognized by that name.

Little information is made public now concerning the Britannia copper mine, near Howe sound, but at last advices it was being operated at full present capacity with non-union men, notwithstanding the published mis-statements of union sympathizers to the contrary. The Consolidated Mining & Smelting Co. has bonded some claims in the vicinity of the Britannia and commenced development work on them. The Tacoma Steel Co. continues to work its Marble Bay gold-copper mine on Texada island. The Surf Inlet Gold mines has done a lot of development work on Princess Royal Island. Endeavors have been made to interest men with capital in copper claims on Moresby Island of the Queen Charlotte group. Prospecting for coal and drilling for oil on Graham island of that group has been continued. In Hazelton district of the Skeena river country, a commencement has been made to ship silver-lead ore in quantity, ten cars having been sent out by the Silver Standard consigned to Trail, while two or three other properties are being prepared for shipping on a commercial basis. Placer-gold mining at Omineca, to the eastward, is attracting attention, as is also coal in the Groundhog district, to the northward.

PORCUPINE

DOME MILL EXTENSION.—THE JUPITER MINE.—KIRKLAND LAKE DISTRICT PROSPECTS.

At a meeting of the directors of the Dome Mines Co. held in New York last month, it was decided not to issue any part of the new capital for the purpose of making additions to the mill. They also decided to install only 40 additional stamps instead of 60 as was first reported, while some changes will be made in the treatment. The present mill is an all-silting plant, the product being treated in Pachuca vats and Merrill filters. In the proposed addition, sand leaching will be used, and it is believed that the present slime plant will be sufficient to handle all of the product from the enlarged mill.

At the annual meeting of the Jupiter company, held at Montreal on June 26, it was shown that the Drummonds, at Montreal, had paid \$300 cash and 50,000 shares for the property. In addition, there has been expended a total of \$203,157, distributed as follows: development, \$175,482; buildings, \$9042; plant and equipment, \$18,633. The balance-sheet shows \$40,841 cash on hand and 157,214 unissued shares in the treasury, which will be issued to meet the cost of a new mill. Development to date has been satisfactory, and on the 300-ft. level of the main vein there is an ore-shoot 300 ft. long, which is expected to yield about \$15 per ton. At the present time no work is being done on the other veins where the ore-shoots are smaller and the gold content more erratic.

The new gold discovery at Kirkland Lake continues to excite considerable interest, but so far very little work has been done on the various properties. The Foster, which is the pioneer mine of the district, is confining its attention to No. 2 vein, from which several shipments of ore assaying about \$500 per ton have been made. A five-stamp mill is in operation, and good results are being obtained. Shipments of high-grade ore have paid for all expenditure to date. The shaft is down about 175 ft., but with the exception of a small open cut, about 75 ft. long on the surface, no lateral development has been done. The shoot will average about nine feet in width, and assays from \$400 to \$500 per ton, and it is stated that the country rock is profitable for a few feet on each side of the vein. Several other veins have been found on this property, but so far no work of any importance has been done,

General Mining News

ALASKA

The Koyukuk-Chandalar region, which includes the drainage basin of upper Koyukuk river and the Chandalar river, both tributary to the Yukon from the north, has been recently described by A. G. Maddren in Bulletin 532 of the U. S. Geological Survey. The winters are long and severe, while the summers, from May to the middle of September, average 55°F. There is a good deal of timber growing, a fair amount of animal life, and the population of whites and natives is about 820. The district is reached by the Koyukuk river, but is difficult of access. The most widely distributed bedrock of the region is a series of metamorphosed sediments, including some altered igneous rocks. The valleys are largely covered by boulders, cobbles, gravels, and silts left behind by melting glaciers. Placer gold was found in 1899, and the yield to the end of 1912 is about \$2,700,000, the latter year producing \$200,000. Some underground mining is done. Methods of moving gravel on the surface are by shoveling, sluicing, hydraulicking, scraping by horse or steam, steam-shovels, derricking, and dredging.

CORDOVA

Telegraphic advices from Cordova state that there is great excitement there and throughout the Copper River valley over the placer gold discovery on Shushanna creek,

MAP OF ALASKA.

a tributary of White river, and hundreds of persons are stampeding to the new diggings. Two prospectors who recently arrived at McCarthy to get supplies reported pans running from 75c. to \$7 at bedrock on Bonanza and Eldorado creeks, and other streams that empty into Shushanna creek. Axel Walstrom, on Claim No. 6, Bonanza, states that his pans run from \$4 to \$5.

NOME

The shortage of water on this part of Seward Peninsula is serious, being only about 25% of that of last season, and the output of gold for the year may be appreciably reduced from the amount produced in recent years. In addition to this drawback, the frost last winter penetrated so deeply into the ground that it is thawing slowly, and this delays the progress of the dredges. This latter condition prevails in all parts of the peninsula. The Pioneer Mining Co. is only employing about 100 men. The Seward company is hydraulicking at the mouth of Shovel creek. All the dredges on this creek are operating.

VALDEZ

At the Gold King mine, rich ore has been opened, and the stamp-mill is nearly completed. Charles Crawford is superintendent.

ARIZONA

COCHISE COUNTY

Gas has been troublesome in sections of the Copper Queen mine, especially on July 13. Great credit is due

to Messrs. Hughes, Finnity, Sherman, and Moon, and others, who investigated the trouble and helped in rescue work. A pulmotor helmet was used.

Investigations into the gas trouble at the Holbrook shaft, of the Copper Queen, on July 13, have shown that the gas came from the old fire area of several years ago. Bulk-heading has now shut off the flow, and a chum-drill is boring to open the gas pocket, and give it an escape to the surface. The new Nordberg compressor was installed in 20 days, and is working without trouble. The Sacramento shaft hoist is also in commission. On the hill south of the Lowell shaft, the new air-equalizing system is ready for installation, and will be of great benefit to the Copper Queen equipment. The slag dump at the old smelter has been almost re-treated.

GILA COUNTY

A group of copper claims in the Christmas district, partly in this and Pinal county, have been bonded for \$1,000,000 to the Gila Copper Sulphide Co. B. P. Cheney, of Boston, is president, and Leo B. Mulhearn, assistant secretary of the Company. Rich gold-bearing ore has been opened in the claims of Claude Battalieur, in Powers' gulch, 16 miles from Globe.

The Inspiration Consolidated Copper Co. has ordered an electric hoist from the General Electric Co., capable of hoisting 10,000 tons in 14 hours from 630 ft. depth. It will be of the Ward-Leonard control type, and automatic in action. Thirteen air-locomotives for underground haulage have been ordered from the H. K. Porter company. Other contracts will be let as soon as possible. At the Copper Reef mine, 13 miles south of San Carlos, the main cross-cut adit is in 1400 ft., while the California drift has been driven 1000 ft., all faces being in ore. The winze is down 250 ft. from the adit. Fifteen tons of ore has been sent to Globe to be smelted in an electric furnace being tested there.

GREENLEE COUNTY

The Detroit Copper Co. will shortly blow-in the new furnace. A large number of men are at work preparing for the start, construction work being carried on day and night. E. W. Honeyman is in charge of the reduction works.

PIMA COUNTY

The zinc mines of the Spokane-Arizona company are regarded as promising. Extensive deposits, assaying as high as 40%, were opened recently and reports of competent engineers who have examined the ground state that the veins of the Mohawk silver mine, owned by the Lewisohns of New York, dip into the ground. The main adit of the Mohawk, reopened since the ore was cut in the Spokane-Arizona, is now within 200 ft. of the end boundary.

As the result of 2000 ft. of development work at the Arizona-Belmont, substantial ore reserves have already been proved and plans are under consideration for erecting a 200-ton mill. The 500 and 600-ft. levels are reported to show higher grade ore than the upper workings. On the 600-ft. level the vein has widened to over 10 ft., carrying \$16 ore. It is stated that mining and reduction costs will average only \$2 to \$2.50 per ton. The ore contains between 10 and 15% lead with 8 oz. silver per ton. Tonopah people are interested in this property.

YAVAPAI COUNTY

The Swansea Consolidated Co. has let a contract to sink No. 6 shaft a further 1000 ft. This is where the highest grade of copper sulphide ores were proved some months ago. George Mitchell, president of the old company, has taken over the Boise & Swansea railway. Ore from the Humboldt Consolidated Co.'s mine will be sent to the El Paso smelter instead of the Needles plant.

YUMA COUNTY

(Special Correspondence.)—At the old Hedges mine, there is great activity, and the work of treating ore has begun. Fifty of the old stamps have been removed, and a new tube-mill, which will handle 150 tons of ore per day, has been installed. A large sum of money has been spent on the pipe-line and pumping plant. More than 100 men are employed. Work is being done on all the levels

of the old workings, and it is confidently believed by all concerned that the property is again on a permanent working basis. Preparations for the immediate working of the American Girl mine is shown by 14 cars of machinery standing on the side of the railroad waiting to be hauled by wagon to the mine.

Ogilby, July 17.

The big lime deposit in the Gila mountains, located by H. H. McPhaul, has been inspected. It covers six claims and analyses return 80 to 95% lime.

CALIFORNIA

AMADOR COUNTY

At Volcano, rich gravel has been opened by Grillo Bros., and there is much local interest. It is said that daily yields have been as high as \$300 since the beginning of July.

BUTTE COUNTY

The Sky High mine, owned by G. W. Braden and Gordon Graham, of Oroville, has produced more gold this season than in previous seasons.

ELDORADO COUNTY

The famous Blue Rock mine at Georgia Slide, which has been worked continuously for nearly 60 years, has been leased by five young men of Georgetown and Georgia Slide, namely, Leo and Thomas Flynn, Henry Miller, Peter Morgan, and Thomas Armstrong.

MONO COUNTY

The Rough Creek district, which was the scene of a boom during the eighties, is again causing excitement, ore averaging \$17 per ton having been opened for a considerable distance, between Bodie and Masonic. Claims have been staked over a large area.

NEVADA COUNTY

A large air-compressor has been ordered for the Golden Center of Grass Valley mine. The shaft and drifts, which were abandoned forty years ago, have been pumped out and work of cutting chutes and ore-bins is now progressing. The Truckee River General Electric Co., which has hydro-electric power-plants near Boca, and supplies power to several mining districts in Nevada, reports that Lake Tahoe is very low, and there is only 1.4 ft. to furnish water during the summer.

The North Star company paid its second quarterly dividend for the current year on June 28. This amounted to \$75,000, making a total of \$3,936,989 to date.

SAN BENITO COUNTY

The production of quicksilver in this county was 9754 flasks, valued at \$410,156, in 1912, against 9809 flasks, valued at \$451,312, in 1911, and 10,804 flasks, valued at \$502,494, in 1910, according to the U. S. Geological Survey. The New Idria treated 76,348 short tons of ore, and the furnaces were operated during most of the year. A good deal of development was done in the mine, and good shoots of ore were opened.

SANTA CLARA COUNTY

The quicksilver production of this county in 1912 was 8695 flasks, valued at \$365,625, against 7533 flasks, valued at \$346,593, in 1911, and 4038 flasks, valued at \$187,807, in 1910. Both the New Almaden and Guadalupe mines made large outputs. The latter has two oil-fired fine-ore and two coarse-ore furnaces.

SHASTA COUNTY

Zinc ore will be shipped to Utah from the Donkey and Baker mines at Ingot, it being carried by auto-truck from the mines to railroad cars.

On July 14 the 275-ft. brick stack at the Balaklala Copper Co.'s smelter at Coram was demolished. This stack cost \$34,700, and since the smelter was shut down on account of fume litigation, has shown signs of weakness. Ninety-two holes, each charged with three sticks of dynamite, were drilled on the northwest side, but instead of falling in that direction it simply collapsed about the base. The charge was set off by electricity. H. F. Wierum, of the Tennessee Copper Co., Tennessee, is at Coram mak-

ing investigations into the fume trouble. The Hall process is to be tried on one or two full-size roasting furnaces. There are at present 27 men employed by the Balaklala Copper Co., and the plant is being overhauled.

The Balaklala Copper Co. let a contract on July 19 for a brick smokestack to replace the one razed recently by

BALAKLALA COPPER SMELTER.

reason of its dangerous condition. The new smokestack will be 230 ft. high, 20 ft. less than the old one. The work will be done by Holt & Gregg, of Redding.

Since writing the above notes, the Balaklala has let a contract for erecting a building for installation of the Hall process of fume prevention. The aerial tram-line to the mine is being overhauled, and the locomotive is again in service. Thirty-six men are now employed.

SIERRA COUNTY

Sacramento people have recently examined the Squires lode and placer claims, in Secret cañon, above Forest City. The property is a promising one, and lies in a slate-porphry belt between the Alleghany serpentine and the Old Ironsides slate-diorite belt. The Kinselbach quartz claims are being developed by Gardner H. Smith, of Pasadena. They are situated in the eastern dike of serpentine, near Alleghany. Rich ore has been opened in a claim above Goodyears bar, on the North Yuba river. A good tonnage of \$10 ore has been opened in the North Fork mine, at Forest City. It is proposed to buy the 10-stamp mill at the Rising Sun mine, on Kanaka creek. An expenditure of \$25,000 is necessary to place the North Fork on a paying basis.

The well known Twenty-One mine has been bonded to W. F. Bradley and N. H. Nielnum, of Blair, Nevada. The Red Ledge mine, owned by the Bank Mining & Promotion Co., is having a 4-stamp mill erected at Scott's Flat. J. B. Moulton is in charge. The Kate Hardy is opening well, and a 3-stamp mill is busy. At the High Commission, near Downleville, the vein is 14 ft. wide. The shoot is about 200 ft. long, and will average \$4.50 per ton in free gold, exclusive of pyrite. After 25 years, the Hawkeye gravel channel, at Howland Flat, is being re-opened.

SISKIYOU COUNTY

Good ore is being mined at the Cub Bear, the Highland is employing about 25 men, the Black Bear is being pumped out and electric power connected, and the old King Solomon, on the South Fork of Salmon river, is being re-opened.

TRINITY COUNTY

(Special Correspondence.)—The new 20-stamp mill at the Bonanza King is practically completed, and 10 stamps are now dropping, while the remainder will be in operation within a few days. The new mill is built on the site of the old one, which, together with the assay office and part of the tramway, was carried away by a snowslide last winter. The ore at present being crushed is a remarkably free-milling quartz, the tailing assaying only 20c. per ton. It is the plan of the management to install four Willsley tables, in the near future, to save the sulphides from a body of ore at present being developed. This concentrate assays about \$40 gold and a little silver. An adit is at present being driven to cut the mineralized zone at a depth of 1000 ft., and the completion of this work and subsequent driving is confidently expected to open valuable orebodies. A winze is also being sunk from No. 3 level in ore.

Trinity Center, July 18.

TUOLUMNE COUNTY

(Special Correspondence.)—At the Hope, which is situated less than one mile east of Sonora, an adit is being driven from a low point to develop the vein. The property has been intermittently worked on a small scale, and by means of a shaft, for many years, some of the former operators taking out considerable gold. It was once equipped with a 10-stamp mill.

A payment has been made on the Chillano mine, situated near Tuttletown, by Clint Manley, who proposes to fully prove the merit of the property by more extensive and systematic development. Mr. Manley will personally direct work. A number of assays were recently made of ore from the Hazel Dell, being developed under bond by a company represented by J. M. Rich, the returns showing an average of \$40 per ton. Preparations are in progress for the further development of the property by adits. Some rich ore has been uncovered in the Sonnet mine, in the Columbia district, the quartz showing a good deal of free gold. The property is being developed by Davis, Lane, and others.

The Springfield Tunnel & Development Co. is to install an auxiliary pumping plant of 1000-gal. capacity in the new shaft, to help the pump now in use. The vein at the Wheel Rough mine, near Soulsbyville, has been intersected by the cross-cut driven from the bottom of the new 100-ft. shaft, and is being further opened by driving. The vein is 12 in. wide and the assays show the ore to be high grade. Assays of ore from the Gold Cliff mine, near Tuolumne, show as high as \$66.50 per ton, the vein varying from a few inches to 2 ft. wide.

Pure white marble of fine texture, and said to resemble and equal the finest Italian marble, has been discovered about five miles south of Tuolumne, by Z. C. Ferris. Several claims have been located.

It is reported that work will probably begin this summer on an electric-power project in this county that will cost approximately \$2,000,000, the surveys for which were made several years ago. A wealthy electric company of this state is said to be promoting the project. According to report, water will be conveyed from immense storage reservoirs in the high mountains to a point in the vicinity of Groveland, where a large power-plant will be constructed.

Suit for damages in the sum of \$50,000 has been brought against the Harvard Mining Co. by the heirs of the late Domingo Gonzales, who was killed July 5, 1912, by falling down the mine shaft. It is alleged in the complaint that the fatality was due to negligence on the part of the mining company, in that the shaft was not provided with any safety contrivance to prevent a fall to the bottom.

Sonora, July 15.

COLORADO

LAKE COUNTY (LEADVILLE)

A large tonnage of low-grade ore has been opened in the Vega section by the Yak company, and metal contents are improving. The monthly tonnage from the Yak tunnel by company and lessees is nearly 11,000 tons. The Stars Consolidated is producing about 4000 tons per month. Lessees at the Chrysolite, Uncle Sam tunnel, Gilt Edge, Little Jonny, White Quartz and others are busy.

At the Iron Mask mill, Red Cliff, a new roaster has been installed and the capacity of the separator has been increased, which permits the mill handling a much heavier tonnage per day.

OURAY COUNTY

In the Mountain Top cross-cut, which is in 2155 ft., the vein has opened out to 5-ft. width, averaging \$8 per ton in gold and silver, and is improving.

SUMMIT COUNTY

The *Summit County Journal* says that the second clean-up for June gave returns of \$30,975 shipped by the Colorado Gold Dredging Co., French Gulch Dredging Co., and the Reliance Gold Dredging Co.

TELLER COUNTY (CRIPPLE CREEK)

The Portland Gold Mining Co. has declared the usual 2c. dividend, which amounts to \$60,000, and will be paid

in August. At the Portland mill, another Chilean mill is being installed driven by a motor, and the transformer station is being enlarged. A washer has been installed at the C. K. & N. mine, on Beacon hill, and it is the intention of Mr. Rapp to go over the entire dump, save the fines and sort the rock. This is considered one of the richest dumps in the camp. During July, mines of the district will pay \$161,800 in dividends. The Strong shaft is down 30 ft. in hard rock, and is to be sunk to 100 ft. before opening out.

IDAHO

IDAHO COUNTY

(Special Correspondence.)—Mrs. Parr is shipping ore from her mine to the custom plant. This ore is mined from the stope under the shoot from which the high-grade ore was taken in the original workings. The American Eagle is sinking below the 200-ft. level, and driving on that level, opening the orebody before starting the mill. Development is under the ground which contained the rich ore mined by A. W. Boyd a few years ago. Stanley Litchfield is still driving on the vein in his adit, and the ore 'pans' well. The South Fork company has found the vein lost last year, and is driving on ore. It is also mining ore in a raise under the rich shoot worked by Mr. Espey four years ago. Frank Peck, at Orogrande, is developing his Knob Hill mine. Joseph Larsen is opening ore in readiness for a mill-run. The Golden Rule placer mine is opening good gravel. Teideman, Brown, and Murphy are opening a rich gravel channel with giants, and it is reported by them that results are improving daily. The New York & Georgia claim of the Smith Bros. is opening well, and they hope that a deal now pending will be successful. The North State at Dixies, is being worked under Frank Hyde, who is mining high-grade ore on this well known property. Machinery is arriving for the new mill of the Majestic. At Ramey ridge, across the Salmon, several properties are opening some soft porphyritic ore which assays over \$19 per ton. Many prospectors are developing their claims in the hills. Walter Hill, assisted by James Frembeth, Charles Thompson, and R. Kemp Welch, is working the old Lacile placer, taking out some good gold in large nuggets. They are operating by drifts under the upper bench of Salmon river. Several others are also working placers in that old locality.

Elk City, July 6.

MICHIGAN

HOUGHTON COUNTY

Telegraph advice from Houghton states that the copper mines are shut down on account of a strike called by the Western Federation of Miners. One of the deputies sworn in has been killed. The monthly production of copper from this district is approximately 20,000,000 pounds.

MONTANA

SILVERBOW COUNTY

The results for the last ten days of June of the Butte & Superior mill again showed an improvement over anything previously recorded. During this period the company treated an average of 588 tons per day, with a recovery of 92.69%, the concentrate averaging 49.09% of zinc. For the entire month the company produced 6,713,881 lb., with an average recovery of 90.25%, and with concentrates averaging 49.10%. Considering that it was only three months ago that the recovery was less than 80%, and that the concentrate was running less than 46%, this performance is gratifying.

Troubles at the Bullwacker and Butte-Duluth leaching plants include the tailing, which cannot be washed clean without getting a lot of dilute solution, which is difficult to handle. Only 80% of the dissolved copper is recovered. It is suggested that the wash-water be run over scrap iron, but this is not practicable, as the free acid would eat the iron.

NEVADA

HUMBOLDT COUNTY

Ore production of Rochester to date totals 100 carloads, valued at \$130,000. In a winze, below the adit level, the

Big Four lease has opened 9 ft. of ore averaging \$45 per ton, while 3 ft. assays 919 oz. silver and \$8 gold per ton. A railway has been constructed from Nenzel to the mouth of Limerick cañon, where it connects with the ore road previously made to the mines. The Rochester Hills Mining Co. intends to produce 200 tons of ore per day from now on. A double-drum electric hoist and 7-drill air-compressor has been ordered by A. A. Codd, the president.

NYE COUNTY

The Nevada-California Power Co., according to the *Tonopah Miner*, has taken every precaution possible to prevent the interruption of its power service through damage by electrical storms, which have in the past frequently caused a shut-off of power supply for hours and even days at a time.

Recently there was installed at the sub-station at Tonopah four new outside Westinghouse transformers, each of these having a capacity of 500 kw., with a special type of outdoor lightning arresters. One of these transformers will be kept in reserve, and the plant now has seven inside transformers and four outside, making the total capacity of the station 5000 kw. All oil-brake switches on the high-tension line have also been abandoned, and the latest type of safety brakes have been installed. The entire installation has cost \$30,000. The Company is now delivering an average of 4300 hp. every 24 hours to the mines of the district.

The Kirchen-Schwab interests have acquired the Tonopah Extension Mining Co.'s stock owned by A. D. Parker, of the Florence Goldfield Mining Co. It is probable that the Extension mill will be increased to 300-ton capacity.

The new ore-shoot on the 1170-ft. level of the Merger has been opened in the west drift for 60 ft., showing 10 ft. of \$56 to \$85 ore, while a 15-in. streak on the hanging wall is very rich. Shipments amount to 50 tons per day. The West End made \$35,015 profit in June. The Tonopah Mining Co. also made a profit of \$89,127 from the treatment of 14,576 tons of ore.

WHITE PINE COUNTY

The new manager for the Consolidated Coppermines Co., Edwin F. Gray, has arrived at Ely and is examining the properties. He was formerly with the Nevada Consolidated Copper Co. At present there is a contract with the Steptoe plant to treat Giroux ores, but a plant for the former company is most desirable.

John D. Tilford, who discovered the Bonita tungsten deposits on Snake creek, has arranged to install a 2-stamp mill and concentrating tables. The ore on dumps should produce two carloads of concentrate.

NEW MEXICO

GRANT COUNTY

The application of the Chino Copper Co. for waters of the Lambrecht, or Lambright draw, has started a number of rumors concerning the intentions of the Company regarding water for use in its mill at Hurley. It is also stated that, if the request is granted, a large concrete dam will be constructed, to which certain people object.

UTAH

JUAB COUNTY

The first cyanide plant to be erected in the Tintic district is now nearing completion and should be ready to go into commission within the next week. This plant has been constructed by Messrs. Griggs, Carter, and Castleton, and the first material to be treated will be several thousand tons of dump ore which has been purchased from the May Day company. The cyanide process is more or less experimental on Tintic ores, but good results are expected. Ore worth \$35 per ton has been opened on the 500-ft. level of the Iron Blossom. This ore parallels the main vein formation. The Black Jack has been shut down for the present. Lessees are to work the old workings of the Opohongo mine. Miners at the Mammoth end of the Tintic district are asking for Sundays off.

SALT LAKE COUNTY

A 6-in. pipe is being laid for the Utah Copper Co. at

Bingham, to carry water from the Utah Metal Mining Co.'s tunnel. The pipe will be about five miles long.

SUMMIT COUNTY

The Ontario mill is treating 150 tons of ore per day. The fume trouble is being investigated. The California-Comstock shaft, in Thaynes cañon, is to be sunk 1000 ft. deeper.

BOLIVIA

The Arica to La Paz railway has reduced the established freight rate 50% on ores from the Corocora mining district consigned to Arica, and 50% on coal. The railroad company is considering the reduction of rates on petroleum. These reductions were the outcome of negotiations between the Bolivian government department of public works and the Company, according to the *Pan-American Union*.

CANADA

BRITISH COLUMBIA

(Special Correspondence.)—Large benefits for Spokane operators engaged in the development of lead-silver and copper properties in the New Hazelton district of British Columbia are foreseen from the proposed erection of a smelter, the feasibility of which is being investigated by engineering representatives of English capitalists, according to a statement attributed to F. C. McKinnon. Paying \$11.50 per ton for the transportation and treatment of their ore, the Spokane operators anticipate a cut of 50% on these charges with a smelter at hand. The English corporation has invested a large sum in the development of the Hudson Bay mine, on Hudson Bay mountain, 30 miles south of New Hazelton. Favorably impressed with the earnestness of the people, the Grand Trunk Pacific Railroad has sent engineers into the field to survey the route for a railroad to the property. The British Columbia Copper Co. will erect a mill at Boundary Falls to reduce the silver in the ore from the Lone Star and Washington mines, and in this way make a product more suitable for smelting with other ores of the district.

Spokane, July 20.

Walter J. Nicholls has closed a deal for four claims on North Star mountain, two miles north of the international boundary line in British Columbia and six miles northeast of the Idaho-Continental mine. Little development has been done on the properties, but the surface showings, together with the location, indicate that they may become valuable. Assays from outcroppings run 46.8% lead and 11.8 oz. in silver. The Granby smelter treated 44,658 tons of ore during the first two weeks of July, and shipped 610,000 lb. of copper. As a result of opening ore in the lower adit of the Ymlr-Wilcox mine, 800 ft. of stoping ground has been added to the mine.

At the Hidden Creek mine of the Granby company, a large underground ore-storage and crusher station is to be arranged. On each level above this are to be bins, of a total of 10,000 tons capacity, while with those below the station the total capacity will be 16,000 tons. The crusher is to be of 200 tons per hour capacity, and from the crushed-ore bins below, the ore will be loaded into cars and taken to the smelter by way of the main working adit. On July 1, there were 1125 men on the payroll. A brick-making plant is being erected, and a machine-shop for all construction and future repairs. Steel for the furnaces and converter building is on the property. A hotel of 40 rooms is now open, and a hospital and recreation hall are being built. A model town is being laid out, with all conveniences.

The Standard Silver-Lead Mining Co., operating the Standard mine near Sliverton, is earning \$8000 per month in excess of the \$50,000 dividend per month, which is at the rate of 24c. per share per year.

ONTARIO

During the week ended July 12, the Crown Reserve, Dominion Reduction, and Nipissing mines shipped 43,575, 59,943, and 139,492 oz. of silver, respectively. At the bottom of the winze, 40 ft. below the 575-ft. level of the Temiskaming mine, 6 in. of rich ore has been opened in the diabase. The veins in the diabase are not extensions

of those in the Keewatin formation above. On the 650-ft. level, good ore is being mined. During the four weeks ended June 17, the Hollinger reports the following results: The winze being sunk below the 300-ft. level, is down 74 ft. in ore. No. 7 vein is 30 in. wide, worth \$16 per ton on that level.

Ore treated, tons	11,867
Average value per ton	\$16.50
Extraction, per cent	95
Profit	\$124,015

KOREA

(Special Correspondence.)—The June clean-up at the Oriental Consolidated mills was valued at \$143,500. Details of the May output are as follows:

Ore treated, tons	26,107
Tabowie mill bullion	\$ 36,399
Taracol mill bullion	28,479
Kuk San Dong mill bullion	4,815
Maibong mill bullion	22,798
Taracol tube-mill bullion	54,975
Kuk San Dong cyanide plant bullion	3,800
Kuk San Dong plant bullion	7,767

Total\$159,033

The Candlestick mill and cyanide plant was closed down during the month owing to lack of labor in the mine, but the plants are now running. The actual extraction obtained in the Taracol tube-mill plant was 86%. An improvement is being made in classification and grinding, and experimenting is being done as to the advisability of installing another agitator, in order to lengthen the treatment. At the Charabowie mine part of the water running into the mine from the river bed cracks has been stopped, and the work is being continued in the river bed, where it is hoped to shut off still more water. There has been no rain during the past 29 days, and everything is very dry. The power-plant furnishes lights only, and water for the mill has to be pumped.

MEXICO

CHIHUAHUA

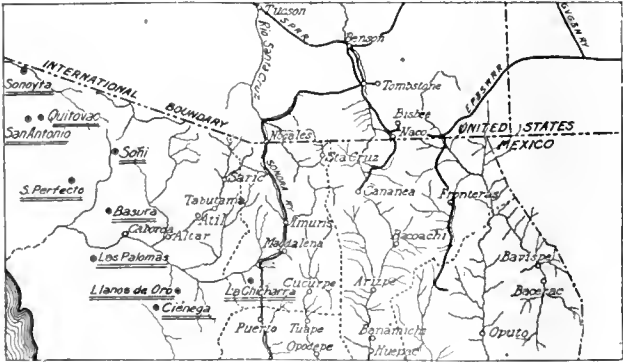

During May the Buena Tierra shipped 3700 tons of lead ore to the smelters, which returned \$24,400 net.

SONORA

During May, operations of the Dolores mine resulted as follows:

Total revenue	P60,242
Mining cost	16,337
Milling	19,692

(Special Correspondence.)—The Democrata mine of Cananea was the scene of another rich find recently, when ore

PART OF SONORA.

averaging 7.5% copper and 5 oz. silver was discovered on the 200-ft. level. Up to the present 45 ft. of the ore has been penetrated which averages the foregoing value. A cross-cut was begun a week ago and is still working in the ore. The Company's smelter is operating with a 250-ton furnace at present,

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

A. S. DWIGHT is in Utah.
R. L. LLOYD was in Virginia recently.
RALPH S. RAINSFORD is in San Francisco.
JESSE SIMMONS has returned from London.
JOHN A. CHURCH is at Great Falls, Montana.
F. D. PAGLIUCHI has returned to Los Angeles.
JOHN H. BANKS is in the West on professional business.
GELASIO CAETANI has returned from northern California.
O. B. HOFSTAND, of Wallace, Idaho, is in San Francisco.
DONALD C. CATLIN has returned to New York from Cobalt.
W. G. RICE, of the Superior & Boston company, is at Globe.

E. J. VALENTINE is on his way to England from the Malay states.

EDWIN F. GRAY is on his way back to Ely, Nevada, from Alaska.

F. W. BRADLEY will remain in Alaska until about September 1.

A. M. BOYLE is now with the South American Mining Co., in Ecuador.

W. P. ALDERSON is local manager for the Mother Lode Sheep Creek Mining Company.

E. B. TINKER has been appointed superintendent for the Boston & Superior Copper Company.

T. K. WEBSTER has resigned his position as president of the Webster Mfg. Co., at Tiffin, Ohio.

H. F. FAY has returned to Boston from a visit to the Lake Superior copper mining district.

C. M. LOEB, vice-president of the American Metal Co., sailed for Europe on the *Imperator*, July 19.

CHARLES W. NEWTON, general superintendent for the Butte & Ballaklava Copper Co., has gone East on business.

C. T. NICOLSON is in charge of the dredging operations for the Andrada Mines Co., in Portuguese East Africa.

H. S. KOHLBERG is assistant superintendent of the Kennedy mine of the East Nevada Smelting Co., Weedon, Quebec.

B. BRITTON GOTTSBERGER, general manager for the Miami Copper Co., has returned to the property after three months absence.

HARRY L. HUSTON, former manager for the Athasar Copper Fields, Ltd., Siberia, has arrived in San Francisco, where he has opened offices in the Mills building.

J. L. DOBBINS sailed on the *Mongolia*, July 16, on his way to Yunnan-fu, China, where he will be principal assistant engineer in the construction of railways in Yunnan.

H. F. WIERUM, of New York City, consulting engineer of the Tennessee Copper Co., is at the Balaklava Copper Co. smelter investigating the Hall process as applied to the ores of this Company.

F. C. LINCOLN has resigned as professor of mining engineering at the University of Illinois, to accept the position of resident engineer for the Bolivian Development & Exploitation Co., with headquarters at La Paz, Bolivia.

The United States Civil Service Commission will hold an open competitive examination for a male editorial clerk, on August 6 and 7, 1913, at certain towns in all states. From the register of eligibles resulting from this examination, certification will be made to fill a vacancy in this position in the Geological Survey, Washington, D. C., at a salary ranging from \$1500 to \$1800 per year, and vacancies as they may occur in positions requiring similar qualifications under certain conditions. The appointee to this position should have such a knowledge of English, printing, and book-making, elementary geology, and geologic nomenclature as will fit him to criticize and correct, acceptably to their authors, the manuscripts of the Survey's reports; to prepare them for printing; to carry along the work of proof-reading through all its stages, and to prepare satisfactory indexes to the reports. The examination will consist of these subjects. Applicants must be 20 and not over 40 years of age at the date of examination.

The Metal Markets

EASTERN METAL MARKETS
(By wire from New York)

NEW YORK, July 24.—The copper market is showing a decided improvement. A large business is being transacted and a slight advance in prices is recorded. Increase in sales may be attributed in a measure to the strike which has been called by the Western Federation of Miners in the Houghton district. If the strike continues it will result in a decrease in the monthly production of 20,000,000 lb. The lead and spelter market is quiet but firm. Cables from London report a big demand for electrolytic copper at £66 15s. (14½c.), which is an advance of ½c. over recent sales. Lead is quoted at £20 10s. and tin, spot, £190 10s. and futures £190.

SILVER

May	4.20	4.34	Nov.	4.91
June	4.40	4.33	Dec.	4.20

The attacks upon the market were not renewed during the week ended July 5. Prices advanced from day to day, up to £20 being again paid for early supplies, while the forward position also improved on some 'bear' covering. The closing price is £18 5s. to £19 15s. for foreign lead, and £19 5s. to £20 5s. for English.

ZINC

Zinc is quoted as spelter, standard Western brands, St. Louis delivery, in cents per pound.

June	6.88	5.00	Dec.	7.09

The European Syndicate has adapted its price to the prevailing market quotations. The lower level thus established is generally considered attractive. Reports from galvaniz-

ing centres, although bad as regards price, are very promising. Prices on July 5 closed at £20 5s. to £20 10s. for ordinaries, and £21 to £21 5s. for specials.

QUICKSILVER

The primary market for quicksilver is San Francisco, California, being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

Week ending	July 10.....
June 26.....	41
July 3.....	41

Monthly averages.

	1912.	1913.		1912.	1913.

May	41.75	40.25	Nov.	41.50
June	41.30	41.00	Dec.	39.75

Final and revised figures of the United States Geological Survey give a domestic production of quicksilver of 25,064 flasks, valued at \$1,053,741 in 1912. Of this, 20,524 flasks was produced in California, and 4540 flasks was produced in Nevada and Texas combined. The total error in estimate for the new year's figures was therefore only 0.3%, and the credit for this must be given chiefly to the producers, who, without exception, promptly, courteously, and accurately gave their early figures and estimates to the Survey. Complete figures for the rest of the world are not yet available. In 1911 these were as follows, in metric tons:

United States	723
Austria-Hungary	793
Italy	931
Spain	1486
Mexico and others	150

COPPER

Quotations on copper as published in this column represent average wholesale transactions on the New York market and refer to electrolytic copper. Lake copper commands normally from 1-5 to 1-4c. per lb. more. Prices are in cents per pound.

June	45.76	45.10	Dec.	49.80

The visible supplies at the end of June, amounting to 12,903 tons, show a decrease of 875 tons, according to Henry R. Merton, on July 5. This market has again been the centre of unusual excitement with wide fluctuations and a very heavy fall in prices. At first the tone was rather better, in response to good consumptive purchases, and prices improved to £195 10s. for three months, but the failure of a Continental firm engaged on the 'bull' side caused some forced liquidation which unsettled the market for practically the rest of the week, at the end of which prices were firm at £186 15s. cash, and £187 5s. for three months.

The visible supply of copper in England, France, and afloat thereto, on July 15, was 29,358 tons, an increase of 1186 tons in the past fortnight. Stocks at Rotterdam, Hamburg, and Bremen decreased 2109 tons.

JUNE COPPER PRODUCTION

Pounds.

Greene Cananea (silver, 89,093 oz.; gold, 473 oz.)..	2,908,000
Nevada Consolidated.....	6,344,836
Utah copper.....	11,637,947

Sulitjelma, Norway (by Elmore process), produced 960 tons of copper concentrate.

During the first half of the current year, the Anaconda Copper Co. produced 136,050,000 lb. of refined copper, sold at an average price of 15¼c. per pound, with an inclusive cost of 10c. per pound, or a slightly higher cost of production than that of last year. Net earnings for the period total \$7,140,000, or at the rate of \$3.50 per share per annum, as against dividend requirements of \$3.

It is now stated by Sidney Norman that the report of a dividend of \$105,000 on preferred and \$45,000 on common stock had been declared by the Federal Mining & Smelting Co., of the Coeur d'Alene, Idaho, is incorrect.

GOLD AND SILVER

Pixley and Abell, of London, report the following on July 10: Since the last circular £784,000 in gold bars has reached London, of which £613,500 was from South Africa; £121,000 was retained for India, and in the absence of any Continental demand, nearly the whole of the balance is going into the Bank of England. Next week £726,000 is due from South Africa and about \$66,000 from Bombay. Since the last circular the Bank has received £992,000 in bar gold, £20,000 in sovereigns from Mexico, £200,000 from Egypt, £7000 from Panama, and £6000 from the West Indies. Bar gold, fine, is quoted at 77s. 9d. per ounce standard.

The silver market is still very quiet, and, after small fluctuations during the past week, today's closing quotations are 26¾d. for spot and 27¼d. for forward, being the same as on July 3.

Business continues on a small scale, the principal buyer being China, while offerings, owing to the smaller supplies from Mexico, are moderate. The premium on forward silver has been maintained at ¼d., though yesterday only 3/16d. was quoted. Easier money conditions and the demand for China being mostly for spot silver having eased the position of holders. A further increase of ¼ crores* in the holdings of rupees is reported from India, the total holdings now being 26.25 crores, against 18.15 crores at the same date in 1912.

In Shanghai, also, stocks have increased and now stand at about £5,650,000. In Bombay, on the other hand, there has been a slight reduction of 200 bars, while in London stocks are still about £3,800,000.

Exports of silver from London to India, China, and the Straits for the year total £4,461,000, against £4,610,700 last year.

DURING the past year, 696,524 tons of ore was hoisted at the Robinson Deep on the Rand, yielding 111,124 oz. of fine gold. An average of 183 stamps daily crushed 623,800 tons in 332 days, and 8 tube-mills working 319 days, an average stamp duty of 10.26 tons per day.

*Hindu term meaning ten millions, or one hundred lakhs of rupees. One rupee equals 32 cents.

Mineral Production of the Eastern Appalachian States

The area covered is for the greater part coincident with the broad belt of old metamorphic and associated igneous rocks extending southwestward from Canada to Alabama. The zinc-lead belt of southwestern Virginia and eastern Tennessee, however, whose rocks are mainly Cambrian and Ordovician limestone and dolomite, lies to the west of this great metamorphic belt. According to H. D. McCaskey, of the U. S. Geological Survey, ore and metal production in 1912 was as follows:

State.	Short tons.	Gold.	Silver.	Copper, lb.	Lead, lb.	Zinc, lb.
Alabama	5,693	\$ 16,724	\$ 103			
Georgia	1,359	14,360	112			
Maryland	14,458	14,830	410	160,831		
Pennsylvania	210,742			473,060		
New Jersey	459,585					139,510,008
New York	100					
North Carolina	16,073	166,014	2,985	75,915	92,000	283,320
South Carolina	12,358	16,915				
Tennessee	635,576	8,265	55,284	18,483,173		4,366,845
Virginia	5,790	218	604	112,835	469,026	497,235
Total	1,361,734	\$222,496	\$59,498	19,265,945	561,026	144,699,863

The total value of all metals was \$13,470,276.

The distribution of the total production among the three main classes of cement is as follows:

	Barrels.	Value.
Portland	82,438,096	\$67,016,928
Natural	*821,231	367,222
Puzzolan	*91,864	77,363
Total	83,351,191	\$67,461,513

*Shipments.

PRODUCTION BY STATES

In the following table the portland cement production for 1912 is given by states, or by groups of states where there are less than three producers in a single state. By

Quicksilver Production in 1912

There were altogether 20 mines and prospects producing quicksilver in the United States, against 25 in 1911 and 19 in 1910. In all three years, also, there were a few mines producing ore but no metal, and a few producing metal from ore mined in previous years. Seventeen of the producing mines reported in 1912 were in California and three in Nevada and Texas. As in 1911 and 1910, no output was reported from Arizona, Oregon, Utah, Washington, or other States.

According to returns to the United States Geological Survey from every producing district, the output of quicksilver was 25,064 flasks of 75 lb. each. At the average domestic price per flask at San Francisco for the year of \$42.05, this production was valued at \$1,053,941. Compared with figures for 1911 and 1910, the yield of 1912 showed an increase of 3808 flasks in quantity and of \$75,952 in value over the production of 1911, and of 4463 flasks and \$95,788 over the production of 1910. The production of California increased from 17,211 flasks, valued at \$800,484, in 1910 to 18,860 flasks, valued at \$867,749, in 1911, and to 20,524 flasks, valued at \$863,034, in 1912. The output of Nevada and Texas combined decreased from 3390 flasks, valued at \$157,669, in 1910, to 2396 flasks, valued at \$110,240, in 1911, but increased to 4540 flasks, valued at \$190,907, in 1912.

There was 139,347 short tons of ore treated in California, averaging 11 lb. of quicksilver per ton treated, or 0.55%, and in Texas and Nevada combined, 16,346 tons was treated, yielding 20.8 lb. per ton, or 1.04%. Of the ore treated, 99.3% was dealt with by shaft furnaces.

the term producer is meant a portland cement manufacturing company, whether the company operates one or more plants. In the table, the term producing plant is applied to a mill or group of mills at one place and operated by one company, but each establishment at a different place is counted as a plant.

State.	Producing plants.	Quantity, barrels.
Pennsylvania	23	36,441,338
Indiana	5	9,924,124

Cement Production in 1912

The total quantity of portland, natural, and puzzolan cement produced in the United States in 1912 was 83,351,191 bbl., valued at \$67,461,513, as compared with 79,547,953 bbl., valued at \$66,705,136, in 1911. This represents an increase in quantity of 3,803,233 bbl., or 4.78%, and in value of \$756,377, or 1.13%. It should be noted, according to Ernest F. Burchard, of the U. S. Geological Survey, that any table in which the production of these three kinds of cement is combined to form a total of barrels is necessarily inconsistent, for the weights per barrel of each kind of cement are different. Portland cement is sold in barrels weighing 380 lb., natural cement in 265-lb. barrels, and puzzolan cement in 330-lb. barrels.

The apparent stock on hand at the end of 1912 was 7,811,329 bbl., compared with 10,385,789 bbl. at the end of 1911. The approximate consumption in the United States was 80,865,527, an increase of 11% over the previous year. Imports totaled 68,503 bbl., and exports 4,215,532 barrels.

CARBONIZED WOOD and remains of leaves have been found in the thin deposits of the Clarence Prospecting Association, eastern Tasmania. These fossils were microscopically examined by H. H. Scott, of the Hobart Museum, who stated that the wood structure and the leaf are of modern forests, and belong to the white peppermint tree. This is a *eucalyptus amygdalina*. There are two different kinds of peppermint trees in Tasmania, whose species is questioned.

Company Reports

THE ZINC CORPORATION, LTD.

This Company operates a large flotation plant for the recovery of lead and zinc content from old bought tailing, and the South Blocks mine and mill, at Broken Hill, New South Wales. It has also recently acquired the Sunny Corner mine, details of which were given in the *Mining and Scientific Press* of July 5. The reserves of tailing on hand at the end of 1912 amounted to 1,844,748 tons, assaying 14.7% zinc, 6 oz. silver, and 5% lead. Ore reserves in the South Blocks mine total 721,191 tons, assaying 14.4% lead, 2.3 oz. silver, and 9.1% zinc.

The principal work on the lead lode consisted of the intersection of the lode in the main west cross-cut at No. 7 level, at a vertical depth of 1050 ft., and the extension of the main north and south drifts from this cross-cut. The lode at this level, where intersected, proved to have a value of 14.1% lead, 2.4 oz. silver, and 13.6% zinc over a width of 18 ft. Since the end of the year a similar cross-cut has been driven from the main shaft at No. 8 level, at a vertical depth of 1180 ft., and has proved the lode at that point to have an average assay value of 14.8% lead, 2.3 oz. silver, and 10.7% zinc over a width of 50 ft., namely, from 70 to 120 ft. west of the shaft. The total width of ore disclosed by the cross-cut is 85 ft., the extension beyond the above mentioned width of 50 ft. assaying from 4.1% lead, 1.3 oz. silver, and 4.8% zinc to 12.5% lead, 2.9 oz. silver, and 8.6% zinc, over 5 and 15-ft. samples, respectively. Drilling at a point 666 ft. south of the main shaft cut 32 ft. of ore between 176 and 208 ft. in the hole, assaying from 2.3% lead, 0.4 oz. silver, and 2.4% zinc, to 16.9% lead, 3.4 oz. silver, and 13.3% zinc. Another hole cut 6 ft. of ore averaging 18.5% lead, 4.11 oz. silver, and 11.8% zinc. The financial results were as follows: :
Sale of concentrate, etc.£644,924
Cost of mining, treatment, office, depreciation, etc. 412,093

Profit	£232,831
Dividends	139,021
Carried forward	90,352

LAKE VIEW & STAR, LIMITED

This Company operates the Lake View Consols and Hannan's Star mines, a 75-stamp mill, and treatment plant at Kalgoorlie. The report covers the year ended February 28, 1913. Results may be summarized as follows:

Development work, feet	4,023
Station and bin cutting, cubic feet	8,612
Ore reserves:	
Lake View, tons	107,050
Hannan's Star, tons	305,720
Average value, per ton	\$6.65
Ore mined:	
Lake View, tons	95,258
Hannan's Star, tons	117,348
Revenue from gold recovered	\$1,210,000
Working expenses	1,010,000
Dividends	153,600

The general managers, Bewick, Moreing & Co., report that the main shaft of the Lake View was sunk a further 209 ft., to 2154 ft., while stations were cut on the 1900 and 2100-ft. levels, and a main west cross-cut was started on the latter level. The Lake View lode was followed below the 1800-ft. level by a winze, which opened 88 ft. of ore averaging \$7.68 per ton. On the 1900-ft. level the north drift of the cross-cut was in poor ore except for 46 ft., which averaged \$7.92 per ton over 5 ft. The winze below this level was down 107 ft. at the end of May 1913, in good ore. Prospecting was done on the 100-ft. level in the northeastern part of the leases, and proved a fair tonnage of ore. At the Hannan's Star leases, about a half-mile distant, work was directed toward opening ore in the upper levels on the Morrison east and west lodes available for stoping. Reserves show an increase of 27,436 tons. Ore worth \$10.32 to \$5.80 per ton, with widths of 6 to 5½

ft., was opened between the 500 and 700-ft. levels. Generally, results at the mines are satisfactory. H. E. Vail is superintendent, and James Bros., of London, are consulting engineers.

SILVER KING COALITION MINES COMPANY

This Company operates at Park City, Summit county, Utah, and the report covers the year ended April 30, 1913. The property contains 2200 acres of patented ground, and has been the subject of a great deal of litigation with the adjoining property of the Silver King Consolidated Mining Co. Legal expenses during the year totaled \$20,799. The general manager, Thomas Kearns, reports that the mine is in splendid condition, and has plenty of ore opened. Owing to the great depth the ore has reached in the western developments, the management found it necessary to

MAP OF UTAH.

sink a shaft in the middle west workings of the property from the present level of the Alliance adit at a point of about 8500 ft. in from the mouth, the collar of this shaft being about 1600 ft. vertical under the surface, and at that point known to be 1000 to 1200 ft. above the contact of underlying quartzite, known to be the foot-wall or underlying limits of the great orebodies. It was found necessary to sink a large standard 3-compartment shaft, which is already down about 260 ft., and a large direct-driven 500-hp. hoisting engine as well as a large electrically driven compressor of the Sullivan type have been ordered. The new equipment will cost \$40,000, but is necessary. Results of operating are as follows:

Ore mined:	
First class, tons	18,229
Lead content, per cent	31.20
Silver content, ounces	64.48
Gold content, ounces	0.057
Second class, tons	81,996
Concentrate from second-class ore, tons....	12,485
Lead content, per cent	35.55
Silver content, ounces	55.76
Metal production:	
Lead, pounds	20,253,704
Silver, ounces	1,871,656
Gold, ounces	1,850
Revenue from ore, metals, lessees, etc.....	\$1,485,675
Forward from previous year	367,011
Mining, milling, marketing, etc.	1,052,686
Loans to bondsmen	300,000
Dividends	500,000
Balance in banks	314,066

Decisions Relating to Mining

Specially reported for the MINING AND SCIENTIFIC PRESS.

THE TAILING QUESTION AGAIN

The ever-recurrent controversy between the farmers and miners over the pollution of streams by mine tailing has just been settled in Arizona by a decision of the United States Supreme Court in the case of *The Arizona Copper Co., Ltd. v. William Allen Gillespie*.

The Arizona Copper Co. was engaged in mining and reducing copper ore near Clifton, Arizona, and a large part of the tailing and waste from the reduction works was carried by the water used in the reducing process into the streams adjacent, or was deposited nearby and was later carried into the streams and thence into the Gila river. The appellee, William Gillespie, owned 276 acres of land on the Gila river about 25 miles below the point where the water polluted by the tailing, as above, found its way into the river. He had reclaimed this land and was irrigating it with water drawn from the Gila river through the Montezuma irrigation canal. The irrigation of the lands of appellee and other farmers of the Gila river valley by this method dates from 1872. With the installation of the reduction and concentration works at Clifton in 1885 the slime and tailing began to discolor the water as above stated, and quantities of them were carried down and deposited upon Gillespie's land through the irrigation ditches, as the court found, to the great detriment and damage thereof.

Gillespie obtained an injunction in 1907 from the District Court, enjoining the Copper company from depositing any slime, slickens, or tailing in such manner that they might be carried into the waters of the Gila river. The territorial Supreme Court modified this order so as to permit the construction by the appellant of settling-basins in such situations as to prevent the deposit of the tailing on farming lands, and affirmed the judgment with this modification. The Arizona Copper Co., while accepting the terms of the modified judgment and constructing large settling-basins to hold the tailing, brought the case up to the United States Supreme Court for final adjudication. The decision just rendered (June 16, 1913) affirms the decree of the territorial court.

The principal questions of law involved were whether the use of water for mining purposes was a higher use than for irrigation, and whether, if the right to use water for mining purposes could not be exercised without polluting the streams with tailing, etc., the lower users should be denied relief from the necessary consequences of the exercise by the miner of a legal right. Both questions were decided in the negative, the court holding that the Arizona statute places both industries on a parity of importance and that the maxim *sic utere tuo ut alienum non laedas* governs property rights in Arizona as elsewhere. The reasoning is in line with that applied to the hydraulic mining cases in California some years ago, and one of those cases (*Woodruff v. North Bloomfield Mining Co.*, 18 Fed., 753) was cited in support of this decision.

It is to be hoped that the settling-basins constructed on the Gila river will prove to be effective. The difficulties that beset the operation of copper smelters and reduction works wherever they impinge on agricultural communities seems to be legion. The bitter controversies that have been waged over the Shasta county smelters in California, the Anaconda smelter in Montana, and the reduction works at Clifton, Arizona, suggest the conclusion that the possibilities of these legal difficulties will have important influence upon the future development of copper mining throughout the country.

ABANDONMENT—WHAT NECESSARY TO CONSTITUTE

Where two mineral locators re-located claims previously held by themselves, and in their location notice declared that they re-located the claims as 'abandoned ground', this declaration was not sufficient to show an abandonment in view of surrounding circumstances showing that

they had never in fact abandoned the ground. The term 'abandonment' includes both the intention to abandon and the act by which the abandonment is carried into effect. There must be a concurrence of intention to abandon and actual relinquishment of the property, so that it may be appropriated by the next comer.

Peachy v. Frisco Gold Mines Co. (Arizona), 204 Federal, 659.

James Lewis & Son's Copper Report

Copper has been devoid of animation during June, in sympathy with the generally prevailing depression and serious shrinkage in the value of stocks and shares. Standard copper prices fell from £67 2s. 6d. for cash on the 2nd to £65 2s. 6d. on the 11th, advanced to £66 2s. 6d. on the 13th, declined to £61 15s. on the 23rd, and recovered to £64 7s. 6d. on the 25th, when three months prompt sold up to £64 15s. A fall to £63 10s. for cash and £63 15s. for three months took place on the 27th, and a reaction to £64 2s. 6d. and £64 10s. on the 30th. Closing prices on July 1 were £63 12s. 6d. for cash and £63 15s. 0d. for three months prompt. Sales amounted to about 38,000 tons.

On June 16 American refiners reduced their quotation for electrolytic copper to 15c. per pound, but sales from second hands were made down to 14¼ and 14¾c., with sellers at £67 5s. per ton c.i.f. for wire bars, without inducing much demand from consumers whose immediate requirements are evidently well supplied from recent large deliveries. With slackening trade generally, and much reduced consumption of copper for the manufacture of sulphate, combined with steadily increasing production, a considerable increase in the stocks appears quite probable during the next six months. United States' shipments for June were advised as 27,815 tons.

Imports into England and France were 3375 tons, and deliveries 202 tons, greater than during the same period last year. The total arrivals in England and France for the month have been 12,992 tons, and the deliveries 14,804 tons fine.

The arrivals in England from Chile during the month have been 1791 and the deliveries 2517 tons fine, and from other countries 7435 and 8000 tons fine, respectively. The arrivals at Liverpool and in Swansea from the United States have been 1940 tons bars, etc., and 620 tons ingots, etc., equal to about 2543 tons fine copper, in London 660 and in France 3330 tons. The Chile charters for the month were advised as 2600 tons, including 1525 tons for the United States, while exports from Chile to June 3 were 18,062 tons.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

A GASHOLDER of 12,000,000-cu. ft. capacity is being erected by the Australian Gaslight Co., of Sydney.

GOLD OUTPUT of the Rand in June was valued at \$15,674,809, making a total of \$97,579,505 for the half-year.

DIPPER TEETH for steam-shovels and dipper dredges must be kept in good condition always in order that economical operation may result.

SULPHURIC-ACID production in the United States during 1912 was valued at \$18,338,019, compared with \$17,369,872 in the previous year.

PEAT is used for fuel, stock food, paper stock, and stable litter. In 1912, according to the U. S. Geological Survey, the United States production was 47,380 tons worth \$228,572.

AN INVESTIGATION into the water-power sites of Japan has occupied three years at a cost of 700,000 yen (\$350,000), resulting in the locating of 892 sites capable of developing 2,020,000 horse-power.

PLACER CLAIMS cannot be located on land belonging to lumber interests, or to private individuals; but probably an arrangement could be made with the owners for temporary occupation.

ROTARY CEMENT KILNS operating in the United States in 1912 were 867, ranging in length from 40 to 240 ft. Of these, 695 were fired with coal, 126 with oil, and 46 with natural gas.

FULLER'S EARTH production in the United States in 1912 was 32,715 short tons, valued at \$305,522, a decrease of 7982 tons from 1911. It is mined in 14 states, principally by Florida, Georgia, Arkansas, and Texas.

DEVELOPMENT WORK in the Lake View mine, Kalgoorlie, during last year cost as follows, the bulk of the work being done in a greenstone formation: Shaft sinking \$108.72; driving, \$17.56; cross-cutting, \$21.20; raises, \$23.40, and winzes, \$26.30 per foot.

ELECTRIC POWER for the Coeur d'Alene mining district, Idaho, is generated by hydro-electric power-plants of the Washington Water Power Co. It is transmitted at 60,000 volts, and at present there are 11 sub-stations with a transformer capacity of 13,900 kilowatts.

BARYTES, or heavy spar (BaSO_4), contains 65.7% of barium oxide and 34.3% of sulphur trioxide. It is principally used as a pigment in mixed paints, and in manufacturing lithopone, a white pigment. Production of barytes in 1912 was 37,478 short tons, valued at \$153,313. This came principally from Missouri.

MUNTZ-METAL SHEETS on piles at Wellington harbor, New Zealand, have been found in excellent condition after being under water for 32 years, so much so, that the original brand could be deciphered. The harbor engineer reports that the muntz-metal supplied during later years is not up to this standard by any means.

POWDERED ALUMINUM is now made by the Aluminum Company of America. It is used in explosives, lithographing, printing, as a paint pigment, and in precipitating silver from cyanide solutions. The concern has in operation at New Kensington, Pa., one of the most complete aluminum bronze plants in the world.

THE new alloy, elianite, is produced in an electric furnace at the electro-chemical works of Rossi, at Legnano, Italy, and is to be used in the manufacture of nitric acid from the air; it is said to differ from similar alloys known in

that its resisting power is not limited to certain acids, and it is a good conductor of heat. The composition is kept secret.

AMMONIA BOMBS are being tried in some of the national forests for the purpose of extinguishing forest fires. They are said to have worked well in the case of brush fires, where the fire-fighters find difficulty in getting near enough to the burning area to beat out the flames. Each bomb exploded will extinguish fire in a circle of about five yards in diameter.

STRONTIUM MINERALS of commercial importance are celestite (Sr_2SO_4) and strontianite (Sr_2CO_3), the latter being the more valuable, though rarer. It is found in San Bernardino county, California, and Maricopa county, Arizona. Strontium hydrate is mainly used in recovering sugar from beet molasses, while strontium nitrate is chiefly used in the manufacture of fireworks.

RELATIVE CALORIFIC VALUES of certain liquid fuels are as follows: Methyl (wood) alcohol, liquid, 5314 calories; ethyl (wine) alcohol, liquid, 7107; hexane (paraffin), liquid, 11,603; benzine, liquid, 10,001; commercial gasoline, 11,368; commercial kerosene, 11,050; crude California asphaltic petroleum, including those from Coalinga, McKittrick, Midway, Kern and Sunset, average 10,350 calories per gram.

MINERAL PRODUCTION of Tasmania during the first quarter of 1913 was as follows: gold, \$175,000; silver-lead ore, 22,897 tons, worth \$360,000; blister copper, 351 tons, worth \$144,000; copper ore, \$10,000; black tin, 787 tons, worth \$556,000; coal, 11,188 tons; wolfram ore, 7.4 tons, worth \$3800; blismuth, 0.75 ton, worth \$1300; osmiridium, 257.45 oz., worth \$10,000; and shale, 10 tons, worth \$4800. There were 5584 men employed.

THE asphalt in an oil may be determined by Holde's method, which consists of distilling off the light oils which may exist in the crude oil and then shaking the residue with 40 times its volume of gasoline, boiling between 65 and 95°C., and as free as possible from unsaturated hydrocarbons. It then is allowed to stand for 24 hours and is filtered. By this means the solid asphalt contained in the oil is obtained upon the filter, together with the clay and other mineral impurities contained in the oil. The asphalt is dissolved by washing with benzol. The benzol is evaporated in a weighed porcelain dish and the weight of the asphalt obtained.

THE iron-nail method of assaying has been used for a number of years, but has not met with the approval of all assayers, according to E. J. Hall and C. W. Drury. The method possesses advantages which may be given as follows: (1) no preliminary treatment is required; (2) a lead button of proper size can be obtained; (3) it is economical. On the other hand, it has its disadvantages, which may be summed up as follows: (1) it is not applicable to ores containing large amounts of impurities other than sulphur, as practically all the base metals will contaminate the lead button; (2) the slag is unsatisfactory in the larger number of fusions; (3) the method was known to give low silver results under certain conditions and the gold results were questionable.

OWING to the fact that every mine has its peculiarities in formation and methods, according to H. T. Van Ellis, in the Transactions of the A. I. M. E., the question of arriving at what charges should be included under the head of development is one that has occasioned considerable thought and comment, and in the cost sheet of the Anaconda Copper Mining Co. this account has been sub-divided to show the expenses of breaking ground, tramming, timbering, shaft-sinking, raising, and cutting stations and skip chutes. It has always been the policy of the Company to charge the entire cost of this work to operations monthly, whether the mines are producing or not, also the cost of the opening up of new mines; and only surface construction and additions are charged to capital, excepting original machinery installed for operating plants.

Book Reviews

ANALYSIS OF METALLURGICAL AND ENGINEERING MATERIALS. By Henry Wysor. P. 82. Ill. The Chemical Publishing Co., Easton, Pennsylvania, 1912. For sale by the *Mining and Scientific Press*. Price \$2.

A study of this volume impresses the reader that it is thoroughly practical, and, while not attempting to deal with the higher branches of analytical work, it will raise the efficiency of students' work to a point where good results should be obtained. The methods of analysis have been carefully selected to include the examination of the more important metallurgical and engineering materials. In this respect may be mentioned studies of steel alloys, tungsten, ferro-manganese, special bearing metals, producer gas, calorimetry of gases, lubricating oil, and the micro-structure of iron and steel, which are all important subjects of the engineering industry. Several of these are accompanied by full-page cuts. A student does not always follow the reactions in chemical analyses, and in this volume, those under discussion are clearly given, as are also instructions in general laboratory work. The volume is published in an unusual style which makes it possible to revise or add to the matter without disturbing the part not affected by the change. There is a table of gravimetric factors, and a bibliography of standard analytical works and papers, but no index. On the whole, the work is worth while.

ELECTRIC METERS. By Cyril M. Jansky. P. 370. Ill., index. McGraw-Hill Book Co., New York. For sale by the *Mining and Scientific Press*. Price \$2.50.

Information regarding electric meters has in the past been obtained from the manufacturers of these instruments, and for this reason it has been incomplete and difficult to secure. Mr. Jansky's new book gives complete information on the theory of electric meters and discusses fully the construction and operation of those meters which may be said to represent American practice. The book starts at the beginning of the subject and, in an elementary way, sets forth the theory of magnetism, energy, power, etc. There are chapters on the theory of alternating currents and alternating current circuits. After describing in detail various volt, ampere, and watt meters, the book takes up at considerable length a discussion of the integrating watt meter. The adjustment and testing of this meter are gone into fully and the effect and extent of errors in this meter are discussed at some length. There are interesting chapters on power factor and frequency meters and synchronizing devices. Prepay meters are also discussed. This book is one that must be read through carefully. It must be studied and cannot be read at odd times by the busy commercial man. It is not a handbook and could be used as a book of reference only by the student who had thoroughly mastered it. The author intended the book as a help in his course on this subject at the University and it was written for students primarily; but it seems to the reviewer that an appendix, containing a brief summary of the important formulae and wiring diagrams for the correct installation of meters in polyphase circuits, would be a valuable addition and of great use to the practical man who needs this information, but who has not the time or frame of mind to patiently study the whole book. Such an appendix would be invaluable to the meter man of a power company or to the engineer or machinery man who has to do with efficiency or guarantee tests in the field and must use meters of this kind.—C. R. S.

AN INTRODUCTION TO THE PHYSICS AND CHEMISTRY OF COLLOIDS. By Emil Hatschek. P. 92. P. Blakiston's Son & Co., Philadelphia, 1913. For sale by the *Mining and Scientific Press*. Price \$1.

This small volume is a reprint of a series of ten lectures delivered at the Sir John Cass Technical Institute in London, and will at once commend itself to the many workers in the field of metallurgy and ore dressing who

need to keep in touch with progress in the field of physics and chemistry, but who lack opportunity, aptitude, and inclination to plough through the mass of current literature in which the skirmish line of progress is steadily being carried forward. Not less important is the fact that the newer concepts are based upon a grasp of principles and details to which many earlier students are comparative strangers. The great importance of the study of colloids in the field of physiological chemistry has somewhat overshadowed the bearing which they have in the inorganic field of industrial chemistry, as well as in purely physical operations. Those in the mining profession who hope to lead, rather than follow, will be grateful to Mr. Hatschek for giving them in a volume of brief compass and low price all the fundamental data concerning colloids which investigation has so far established. If any criticism is justified, it is that the book is too brief, for the subject is so new that many will perhaps be unable to perceive unaided the significance of the phenomena so briefly pointed out. Thus the brief references to adsorption might not suffice to indicate to metallurgists and chemists, for example, that in the fine grinding of copper ore, preparatory to leaching, a sufficient quantity of colloid material may be formed to tenaciously retain by adsorption considerable quantities of soluble copper salts. The possibilities of 'salting out' of colloids in the chemical and physical industrial process is similarly of much importance and deserves fuller discussion. Such topics can, however, only be adequately treated by those who supplement an accurate knowledge of theoretical considerations by a comprehensive knowledge of operating conditions, and this book may therefore be regarded as the first step in attaining such a consummation. And even if there is no visible immediate effect beyond decreasing the misuse of 'adsorption', a word which many engineers use, but few correctly, its preparation will have been well worth while.

National Tubing

THE illustration furnished by the National Tube Co., of Pittsburgh, Pennsylvania, is submitted as evidence of the high quality of the products manufactured by this Company. The illustration is a part of the tubing used in lining of an oil well near Gore, Ohio. The well when completed was shot in the usual manner, and later a second shot consisting of 150 quarts of nitroglycerin with a 20-

ting slime, quite insignificant in such a dilute bath. A bed of thickened slime several feet deep is maintained on the bottom of the vat. This slime is kept diluted by the agitator mixing the slime at the bottom with wash-water admitted through the pump, supplying an excess beyond that required for discharging the slime to waste. The excess water rises in the vat around the falling slime, washes it, and, mingling with the pregnant solution, overflows to the gold-tank or clarifier.

The method of introducing slime to the vat causes

EFFECT OF EXPLOSION ON TUBING.

quart anchor shot was used. The lining was then pulled, and it was found that there was still one joint in the well. This joint lodged about 1500 ft. below the surface, but was finally taken out by means of a bell socket. The well was about 3000 ft. deep and the casing was not damaged in any way. The part illustrated was normally about 18 ft. in length, and, due to the intense shock of the explosion at this point, has been compressed to a length of about 8 ft. Careful examination will show no fracture in the material, notwithstanding the punishment to which it was subjected.

A Continuous Replacing Machine

The L. C. Trent underfeed replacing machine eliminates filtering for treating any slime, as the extraction of solution may be readily performed in the vat itself. The machine feeds previously agitated slime continuously into a vat containing thickening apparatus with means for mixing wash-water at the bottom, and having a controlled water inlet and slime orifices. This utilizes the principle of the Trent underfeed agitators, which not only mechanically thicken pulp, but are so designed for replacing that the disturbance caused by the thickened slime in which it operates does not retard settling above.

A circulating pump is supplied from a circular perforated pipe surrounding the interior of the vat near the bottom, the perforations being on the under side to prevent choking. This method insures perfect distribution, with the disturbance confined to a limited plane. The wash-water is introduced gradually through the pump suction and is properly mixed with the thickened slime. Slime flowing from the agitators is introduced into the vat through the distributor at the surface, and the solids settle from the original solution into barren wash-water, and thicken at the bottom, where they are washed and discharged. The original solution is replaced with water introduced through the pump, and mixed with the thickened slime through the agitator jets near the bottom of the vat; while the released pregnant solutions overflow into the launder surrounding the top of the vat and is read for clarification and precipitation.

The following is an example: In treating 100 tons of $1\frac{1}{2}$ solution to 1 slime per 24 hours in a 24 by 16-ft. vat, there will be fed in 26 gal. of solution and 139 lb. of ore per minute, and there will overflow 26 gal. of solution mixed with a maximum of $6\frac{1}{2}$ gal. of excess wash-water, totaling $32\frac{1}{2}$ gal. of solution extracted. There is discharged as residue 26 gal. of water and 139 lb. of ore, equalling 6 gal., or a total of 33 gal. of ore and water combined per minute. Therefore, the solution has been diluted but about 25%, and the residue remains the same in volume as in the original slime, a high percentage of which can be recovered by simple methods, so that the final discharge will not exceed 35% of water, and the reclaimed water returned for further use. In providing for 25% of excess wash-water, there is a maximum rising liquid column of but 0.025 in. per minute to retard the set-

ting slime, quite insignificant in such a dilute bath. A bed of thickened slime several feet deep is maintained on the bottom of the vat. This slime is kept diluted by the agitator mixing the slime at the bottom with wash-water admitted through the pump, supplying an excess beyond that required for discharging the slime to waste. The excess water rises in the vat around the falling slime, washes it, and, mingling with the pregnant solution, overflows to the gold-tank or clarifier.

The method of introducing slime to the vat causes the heaviest and most granular portion of the pulp to settle around the central bottom area contiguous to the residue discharges, while the lighter slime falls toward the periphery, whence the circulating liquid to the pump is withdrawn. This protects the pump from grit and insures the thin slime being mixed with the discharging solids. The solids in the slime settle through a slowly rising column of weak solution passing a zone of barren water into barren slime. The inflowing pregnant solutions are discharged from the surface of the charge as rapidly as received with the solids removed, and but slightly diluted or increased in volume, the amount of such dilution being subject to regulation. The falling slime, by displacement, causes an upward flow of liquid which washes the solids and resists any tendency to diffusion. There is continually brought from the depths of the vat to the clear overflow a volume of barren liquid equal to the volume of solids being discharged from below. As the lower liquid in the vat is wash-water, diffusion is stopped automatically, and channeling is rendered impossible because the wash-water is intimately mixed with the slime before entering the vat. The L. C. Trent Engineering Co. has under construction eight of these machines, including one for the West End mill, Tonopah, and two for the Gold Cross mill, Imperial county, California.

A New Hoisting Cage

George S. Rice, chief mining engineer of the United States Bureau of Mines, has dedicated to public use a patent just issued by the Government for a hoisting cage which is primarily for use in rescue work, but can be used for other purposes.

In describing his invention, Mr. Rice states that it has for its object the provision of a novel cage which shall have peculiar advantages in regard to portability and ease of assembling and disassembling. He adds that although not limited to such use, it is of especial utility in mine-rescue work as an emergency cage. It frequently happens in case of mine accidents that the regular hoisting equipment may be so damaged or disarranged that it cannot be used. In such cases the provision of an emergency cage which can be made ready in a few minutes will greatly facilitate the work of rescue parties. The cage comprises a collapsible frame consisting of two flat bars, each bent into a form which may be termed approximately elliptical, and the ends welded together, thus forming endless members which serve not only as uprights but also as top and bottom frame parts. The inclosing members for the cage comprise horizontally arranged hoops, each bolted to the upright frame members, thus serving both to brace the frame and to form skeleton sides adapted to prevent falling or displacement of load. It will be seen that the generally elliptical contour of the cage will greatly facilitate its travel past obstructions in the shaft, and that the curved upright portions of the frame will serve to a certain extent as guide shoes. In large cages it may be desirable to use more than two of these frame members.

REPORTS from Boston state that the Utah Metal Mining Company "is now drifting to the west in the face of a good silver-lead vein." This is, of course, much better than drifting down Salt creek in the teeth of a raging gale.

PARTICIPANTS in the visit of the American Institute of Mining Engineers to Japan in 1911 will be glad to learn that the *Umegaka Maru*, the clean little steamer in which the party traveled through the Inland sea and which was later sunk in a storm, has been raised and is being refitted.

INVASION of the 'tight little isle' by American slang is deprecated by the *London Mail*, which lays the blame upon the ubiquitous moving-picture film. Apparently the editor of our British contemporary is not a perspicacious attendant upon 'the movies,' since for the benefit of his readers he defines a 'fume' as a waterfall, and 'clean-up' as the completion of a task.

THE Hyde process of mineral flotation as conducted at the Butte & Superior property has been recently adjudged an infringement on the Minerals Separation American Syndicate, by Judge Bourquin in the United States District Court of Montana. The answer to the old question as to 'when is a patent not a patent' seems to be, until it has been adjudicated as such in from one to a half dozen courts.

A PRACTICAL application of Russell's 'dry lake theory' of salt deposition is recorded in the present number in an interesting account of the recent exploration work which has been conducted in Railroad valley, Nevada. Mr. E. E. Free, who has been in charge of this investigation, has made a valuable discovery which, as described in this article, furnishes the first direct evidence of the existence of a large salt deposit as confirmatory of the 'dry lake theory.' The discovery of this bed of gaylussite presents unquestioned evidence of a saline lake deposit, and there is every reason to suppose that future exploration work will result in the discovery of the more soluble salts of sodium and potassium.

ANOTHER evidence of the security of foreign lives in Mexico is presented in the recent arrest of Charles Biesel and Bernard MacDonald in Chihuahua and their sentence to death on the charge of conspiracy to defraud the government. Just how an attempt to move the bullion of one of the properties of the Mines Company of America out of the

path of the 'revolutionists' was construed as a capital offense punishable by death and also carried with it the right of the 'government' to confiscate an automobile belonging to the offenders, is a new wrinkle in the federal code. However, these are trying times in Mexico and laws are made and unmade with such rapidity that for the ordinary layman to keep posted on Mexican revolutionary jurisprudence is almost superhuman. After protest by the State Department, Messrs. Biesel and MacDonald have been released.

WHILE the general subject of mechanical efficiency as applied to mining and milling machinery is one which receives but little attention by the average superintendent, that it is one of importance in the final reckoning of cost is also certain. The subject of investigating rock-drill performance is one which has been practically neglected, and it is therefore pleasing, indeed, to present to our readers an article in the current issue on the subject of rock-drill testing as conducted at the North Star Mines. While the subject of the mechanical efficiency of air drills is not discussed as such, the data which are being obtained through this investigation have tended to materially increase the efficiency of the drills as well as decrease the complaints from the mine.

CONSTRUCTION of a plant for the manufacture of steel forgings, at Longueuil, on the opposite side of the St. Lawrence from Montreal and about ten miles distant, is said to be assured. The plant, which is to be built by Armstrong, Whitworth & Company, Limited, will cost about \$1,000,000. The iron and steel industry of Canada is showing healthy growth. In addition to the considerable tonnage of iron ore mined to the north of Lake Superior, the Canada Iron Corporation is now mining in Nova Scotia, where the Nova Scotia Steel & Coal Company and the Dominion Iron & Steel Company are also engaged in iron smelting, chiefly imported ore. The earnings of the latter company are improving rapidly, and the Canada Steel Corporation has under construction a concentrating plant for its ore.

GOLD production and its effect on industrial conditions is a topic which gives certain economists a great deal of concern. Business and banking credits are based on gold reserve, and the tendency of the population of India to acquire gold and hoard or bury it has caused much discussion in the past few years. Now the news comes that India is decidedly slacking off as a purchaser of gold, and Brazil and Argentina are also taking less quantities of gold than in former periods. The gold output of the world will therefore be, in a large measure, directed to the banking centres of Berlin, Paris, Vienna, and London, where it will go far toward relieving the present stringency of money markets. It is an interesting instance of how economic factors work together that, when the world's gold production gives every evidence of beginning to decline, a better natural readjustment of conditions is beginning to make a better utilization of the supply possible.

The Lake Superior Strike

The strike of the miners and millmen in the Lake Superior copper district has subsided to the dull routine of picket duty and an occasional encounter between some isolated workman and a crowd of strikers. The demands made include the recognition of the Western Federation of Miners, by which organization the strike was declared; an increase in the wage scale, decrease in the length of the working day to eight hours, the abolition of the one-man drill, and a general improvement in the conditions surrounding the miner. In short, the Federation demands that the same conditions be enforced in the Superior district as obtain through the mining districts of the West.

The Calumet & Hecla company, as the chief producer of the district, is the natural leader in the present controversy, and upon its action will depend to a large extent the attitude of the smaller mining companies, and, as such, a few words as to the Company's position are timely. It will be recalled that this Company made a general increase in the wage scale amounting to ten per cent, in May of last year, when copper was selling at 16 cents and better. This scale, which has in no way been altered with the decline in the price of copper, was largely responsible for the increase in the cost of production for the year from 8.52 cents in 1911 to 9.86 cents in 1912. This cost of production, under present working conditions and with the most modern equipment, is in excess of the cost of most of the large mining companies of the West. The one-man drill, which has been asked to be discarded, was adopted after experience had proved it to be a more efficient drill for the work in hand than the old two-man machine. It would seem that this was the logical thing for the management to do under the circumstances. It has been the history of all classes of industry to discard the inefficient for the efficient, and the efficient for the more efficient. Just why mining should be an exception to this, is one of the questions which the present strike has to decide. The question as to hours and wage scale is, of course, the all-important issue. The strikers' contention is that the time and wage scale should be placed on the same basis as that of the Western miners; the labor being the same, it should command the same wage. The operators hold that the price of metal will not permit of such an increase. The wage scale and working hours of the Western Federation, if adopted in the Lake Superior copper district, would mean approximately a 50 per cent increase in wage and a 25 per cent decrease in the length of the working day. If an increase of 10 per cent in the wage scale alone caused a rise in production cost from 8.52 to 9.86 cents per pound, will it be possible to operate the mines with a fair profit to the shareholders if the demands of the strikers are met as to time and wage and a comparatively inefficient drill is adopted as well? The question at least admits of debate, and is one which we trust will be submitted to judicious arbitration rather than to gunpowder, and an amicable understanding may be reached.

Flotation Processes

Flotation, as is well known, while discovered in the United States, found its first large and important field in beneficiation of the zinc ores at Broken Hill, Australia. In 1904, when the significance of the new development first came to be generally appreciated, it was estimated that nearly 6,600,000 tons of ore was made available for production in this one district. Roughly, this was equivalent to the world's consumption of spelter for two years, as matters then stood. There was in addition the possibility of a wide application of the process in other districts, and, at the time, great fears for the market were entertained. It is now estimated that the production of zinc ore at Broken Hill has attained a maximum, though but little more than one-third of the total estimated reserve has been worked into metal. While prices are depressed at present, it needs but a brief study of production and markets to make clear that the Broken Hill surplus has been placed on the market without general injury. The consumptive power of the world, as regards metals, has grown so enormously in the last decade that it is rather a question as to how much consumption would have been restricted by 'run-away prices' if flotation had not come to the rescue.

Whether the same sequence is to follow in the copper field is an interesting question. Copper production has increased by leaps and bounds—from 280,000 metric tons in 1891 to 529,000 in 1901 and 970,000 in 1911, the latest year for which complete figures are available. Consumption has, however, grown *pari passu*, and, while the copper surplus has been at times a dreaded nightmare, the visible supply amounts normally to little more than one month's consumption. A copper famine has been repeatedly predicted even by careful and conscientious students. In the meantime, development of the so-called 'porphyry' mines of the United States has greatly increased the production, and enormously increased the total amount of metal available by lowering the necessary content of the ore. It is worth noting that this has been due less to invention than to better business organization. The great mills at Garfield, Utah, and at Ray, Arizona, which have treated 21,000 tons and 8000 tons, respectively, in a single day, contain little that is novel. A one per cent copper sulphide ore is now treated, where formerly five per cent possibly spelled the lowest limit, because of capital investment, rather than of improvement in technology. The process used in the mills is wet-concentration, an old process made to do its best, rather than any fundamentally new scheme of treatment. It is the scale of operations that has converted worthless rock into ore. It is estimated that in 1913 a total of 1,590,327,000 pounds of copper will be produced by 32 American companies, including under that term, as is proper, those in both South and North America. More significant, possibly, is the fact that the total known ore reserve of seven of the great 'porphyry' mines may now be placed at 700,000,000 tons of commercial ore. The Chile Copper Company, whose operations

at Chuquicamata are under the competent direction of Mr. Frederick Hellman, begins operations with 160,000,000 tons of 2.40 per cent copper ore, and with 'probable ore' to the extent of another hundred million tons or more. At this mine, as at the Braden, and at Anaconda, leaching is to be undertaken, but at most of the big copper mines in America the limitation as to saving is that fixed by the imperfections of wet concentration.

Speaking in general terms, the concentrating mills that operate on low-grade copper ores, save 70 per cent of the metal. In a few plants, and in still others at times, the recovery may run up to 80 per cent, but in general 25 to 30 per cent of the copper in the ore is lost. This large field for possible saving has attracted the best talent in the metallurgical field, and leaching and flotation are being tried at a number of places. Perhaps the most significant announcement is that the Inspiration Copper Company, impressed by the results obtained by Mr. E. H. Nutter, is applying the Minerals Separation process to Inspiration ore, as we announced April 19. If this proves as successful in the pilot plant of 600 tons as it has in the 50-ton plant that has been in operation for several months, direct treatment by flotation will be adopted, with an incidental saving of \$1,000,000 in construction cost. Such an example is likely to prove contagious, and numerous tests on other American ores are already being made. The United States supplies over half the world's copper, and America as a whole, easily dominates copper mining. If, as begins to appear, adoption of flotation will render possible a 5 to 20 per cent better saving in American mills, the copper market faces the same problem as did the zinc market in 1904. Entirely aside from the effect of the revival of interest in leaching processes, which, while important, is not likely to be disturbing, preliminary estimates indicate a possible increase of 100,000,000 pounds of copper per year from the United States mines as a result of adoption of flotation. Of this, something over one-half may come from producing mines at which the process has been actually tested and found available. The remainder is from other mines, either in the same district or in which the ore is known to be of the same general character. While flotation is, as yet, an empirical process, and it is impossible to say in advance whether or not a given ore can be treated successfully, the above estimates have been made with care and are believed to be conservative. Applying the ratio of possible saving to the known reserves of ore, analogy to the history of flotation in its application to zinc ore is found in that a trifle over two times the world's present annual output of copper is added to the reserve by the expected increase in recovery. It will not do to push analogy too far, but it is easy to believe that this copper will come to the market so slowly as to meet merely the continued per capita increase in consumption and the abandonment of existing mines. We are permitted, therefore, to rejoice in the triumph of the metallurgists without fear of danger to investors. If by this means the large tonnage of waste may be made to yield an additional per cent to the net extraction, a great good has been accomplished.

Progress in Potash Prospecting in Railroad Valley, Nevada

By E. E. FREE

For nearly two years past, the Railroad Valley Co., of Tonopah, has been making an active search for a potash deposit in Railroad valley, Nye county, Nevada. The incentive of this search lies in what has come to be known as the 'dry lake theory,' the essentials of which were developed by Russell¹ with reference to the Quaternary lake Lahontan.

Dry Lake Theory

The theory may be outlined briefly as follows. Many of the landlocked basins which collectively make up the Great Basin show unmistakable signs of having been the homes of great lakes, among which

ory of salt burial, or freshening by desiccation, which assumes that the missing salts were covered by washed-in alluvium after the complete desiccation of the lakes and are now buried beneath the basin floors either as actual salt bodies or as masses of saline alluvium. More recently, at the hands of H. S. Gale² and others, this theory has received the natural extension that such buried salt-bodies *may* contain segregations of potash and other valuable salines. Hitherto this theory has rested almost entirely upon indirect evidence only. With a few minor exceptions, no buried salt-body has been actually discovered. The work outlined in the present paper furnishes the first satisfactory direct evidence of the existence of such a body of significant magnitude.

Railroad Valley

In all essentials Railroad valley fulfills the necessary conditions of this 'dry lake theory.' It is a landlocked basin surrounded by high mountain ranges with no passes low enough to have been channels of discharge. The deepest depression of the valley is a comparatively non-saline mud flat or *playa*, the situation and relations of which are indicated by the accompanying sketch map. The drainage area now actually tributary to this flat is probably not over 4000 square miles; but previously, when a moister climate maintained a drainage of greater vigor, the tributary area was approximately 6340 square miles. Even now the cut-off portions of this former drainage are cut off only because of stream decay and the failure of all drainage. The drainage is barred by no important divides.

At the present time there is no permanent lake in the basin. Heavy rains occasionally produce floods in the central *playa*, and during a part of the year water from springs stands an inch or two deep over a small area on the western margin. It is possible, however, to trace around nearly the entire circumference of the basin remnants of two well marked shore terraces and of several intermediate ones which are less pronounced. The highest of these terraces is approximately 150 ft. above the present *playa* and furnishes conclusive evidence of the existence in recent geologic time of a lake of considerable depth and probably about 225 square miles in area. From present data, the history of this lake is not decipherable in detail, but the system of fainter terraces below the highest indicates that the fluctuations of the lake were not essentially dissimilar from those of Lake Lahontan and the other lakes which have been more closely studied. As with them, the disappearance of the lake is to be ascribed to climatic causes, and the salts which its waters contained must be buried beneath the basin floor.

The hope that this hypothetical salt-body may contain potash rests mainly on the character of the rocks composing the drainage area of the basin.

PART OF RAILROAD VALLEY, SHOWING SITUATION OF DRILL-HOLES.

Bonneville and Lahontan were the largest and have been most studied. Most of these lakes were as completely landlocked as are the present minor lakes of the Great Basin. Of the larger lakes, only Bonneville rose high enough to attain discharge to the ocean. The others, always undrained, must have accumulated in their waters large amounts of soluble salts derived from the normal solution of the rocks of the drainage area by rain and streams. The disappearance of these lakes can be ascribed only to a climatic change in the direction of greater aridity, with the consequent evaporation of the lakes, and, since there can have been no way of escape for the contained salt, that salt must be within the lake basins still. However, the most careful examination of the Great Basin discloses no bodies of salt sufficiently large to represent the saline residue of the vanished lakes. The surface salinity, while sometimes considerable, cannot account for more than a small fraction of the salts which the lakes must have contained. Confronted by this dilemma, Russell developed the the-

¹The Geological History of Lake Lahontan,' U. S. Geol. Survey, Monograph 11 (1885).

²U. S. Geol. Survey, Bulletin 530-A (1911).

Rhyolites of high potash content are prevalent, and probably predominate. The eastern border of the basin is the high and steep White Pine range, rising sharply from the deepest depression of the basin and consisting largely of Silurian limestones and other Paleozoic sediments. Rhyolites or other igneous rocks are not prominent, though several limited areas have been identified, especially in the southern portion of the range. The western border of Railroad valley proper is the Pancake range, but this is not the boundary of the drainage area. Hot Creek valley, which lies westward from the Pancakes, is tributary to Railroad valley, the drainage crossing the Pancakes through Twin Springs pass. The western border of Hot Creek valley, and of the Railroad valley drainage, is the prominent Hot Creek range, centrally of sediments similar to those of the White Pine range, but containing large areas of rhyolites and other volcanics at both northern and southern ends. The intermediate Pancake range is almost entirely of volcanics, even the occasional water-laid beds being largely of volcanic tuff. Both rhyolite and basalt are abundant, the latter being represented by some recent flows and cones, but the rhyolites are far more extensive than the basalts. Reliable quantitative estimates will not be possible until more accurate geologic maps are available, but it is safe to assert that the high-potash rhyolites cover a sufficient proportion of the basin to insure the abundant presence of potash in the drainage and in the waters of the ancient lake.

Results of First Drill-Hole

The first important step in the potash prospecting was the sinking of a drill-hole, about three miles north of the mud flat, at the point marked 'drill hole 1' on the map. The hole was sunk with a churn-drill to a depth of 1204 ft., and required for drilling a little over five months, from March to August, 1912. The materials encountered were alternating sand and clays, with the clays largely in excess. Below 100 ft. nearly all sand carried fresh artesian water. Between 1140 and 1144 ft., there was encountered a cemented sand, the cement of which was determined as gaylussite by J. Claude Jones, of the Mackay School of Mines, Reno, Nevada. Between 1175 and 1190 ft. was a similar cemented sand, but with the cement of calcite instead of gaylussite. With these two exceptions, no chemical lake deposits were encountered in the hole. Between 1190 and 1204 ft., the materials were alternating sand and reddish clays. Further progress was impossible because the casing could not be forced through the cemented material between 1175 and 1190 feet.

This record was interpreted as indicating that the drill site was too far north and had missed the edge of the basin in which the salt had accumulated and been buried. Accordingly, a second drill-hole farther south was decided on, and, after some shallow exploratory drilling with a hand drill, a site was selected near the centre of the mud flat as shown on the map. Drilling operations in such a place are extremely difficult. The moving of the equipment over the spongy surface of the mud flat was slow and difficult, and was rendered more so

by floods. Fuel wood had to be brought from over 30 miles away. It was necessary to construct a ditch eight miles long in order to bring water for drilling purposes from the artesian flow of hole No. 1. These difficulties consumed much time, but were successfully surmounted, and the drill was started at 8:20 a.m. on July 7, 1913. At midnight, July 12, the drill had reached a depth of 843 ft., and drilling was discontinued, the record being deemed sufficient for present purposes. The machine employed was the combined rotary jetting equipment of the American Well Works, drilling a hole 5½ inches in diameter. No casing was employed, it being found unnecessary. Careful watch was kept of the material penetrated, not only by continuous sampling and examination of solid materials brought up, but by chemical analysis of descending and ascending drill water at 10-ft. intervals. The record of the hole is as follows:

Surface to	2½ ft.	Brown clay containing skeleton crystals of calcite.
2½ "	22 "	Gray clay.
22 "	44 "	Soft black mud.
44 "	52 "	Gray clay.
52 "	55 "	Black mud.
55 "	56 "	Gray clay.
56 "	69 "	Black mud.
69 "	85 "	Dark gray clay.

422 "	426 "	Hard gray clay.
426 "	429 "	Cemented black clay.
429 "	463 "	Hard black clay, probably with occasional gray streaks.
463 "	475 "	Light gray and brown clays with cemented streaks.
475 "	487 "	Cemented black clay.
487 "	492 "	Black clay.
492 "	506 "	Cemented black clay.
506 "	517 "	Hard gray clay.
517 "		Two-inch stratum of hard rhyolitic volcanic ash.

517	"	529	"	Hard gray clay.
529	"		"	Thin stratum of rhyolitic volcanic ash.
529	"	550	"	Gray and black clays, probably alternating layers.
550	"	556	"	Cemented black clays.
556	"	567	"	Soft white and brown clays.
567	"	582	"	Stiff white and brown clays.
582	"	639	"	Soft white and brown clays.
639	"	653	"	Light gray clay with occasional cemented streaks.
653	"	659	"	Hard light brown clay, partly cemented.
659	"	679	"	Tough gray clay.
679	"	682	"	Soft gray clay.
682	"	684	"	Hard brown clay, somewhat saline.
684	"	718	"	Tough gray clay.
718	"	765	"	Gray clay with crystals of gaylussite, and carrying many hard layers cemented with gaylussite.
765	"	781	"	The same, with the proportion of gaylussite crystals increasing downward.
781	"	790	"	Crystalline gaylussite.
790	"	794	"	Rapid alternations of crystalline gaylussite and gray clay with loose gaylussite crystals.
794	"	799	"	Crystalline gaylussite.
799	"	841	"	Crystalline gaylussite with occasional layers of gray clay carrying gaylussite crystals.
841	-	843+	"	Crystalline gaylussite.

This record falls easily into four main divisions: 1, alternate gray and black clays, 21½ to 251 ft.; 2, the same with cemented layers, 251 to 556 ft.; 3, brown, white, and light clays, 556 to 718 ft.; 4, crystalline gaylussite, with some admixture of gray clay, 718 to 843 feet.

Significance of Gaylussite Beds

It seems beyond question that the gaylussite bed between 718 and 843 ft. represents the deposit of a saline lake. In no other way could there be deposited so large a body of this mineral in such comparatively pure condition.³ Gaylussite is relatively insoluble in water or saline solutions, and is therefore the first or one of the first minerals to be deposited by an evaporating lake. With the exception of calcite and gypsum, any other minerals which may have crystallized from the lake ought to overlie the gaylussite, and it follows that the gaylussite bed furnishes a datum representing an early stage of the lake's desiccation. The clay layers and admixture in the gaylussite doubtless correspond to floods, wet seasons, etc., which brought unusual amounts of alluvium into the lake and possibly interrupted for short periods the deposition of the gaylussite. However, the essential purity of the bed implies strongly that such interruptions were minor and transient and that the evaporation of the lake proceeded fairly steadily and probably fairly rapidly.

From the gaylussite bed alone it is not possible to say that the lake evaporated completely to dryness, but a strong implication to this effect is carried by the non-salinity of the superposed clays. It is inconceivable that the lake could have contained in its waters the constituents of gaylussite, and them only. There must have been present also some or all of the usual more soluble salts, the chloride, sulphate, and

carbonate of sodium and the salts of potassium. If the lake continued steadily to evaporate, the deposition of gaylussite would cease only with or after the commencement of deposition of some more soluble salt. In any case, the deposition of all or a large part of the gaylussite would leave the lake a mother liquor, not necessarily highly concentrated, but containing large total amounts of the various more soluble salines. If the lake then were freshened, thus causing a cessation of chemical deposition, these more soluble salts would remain in solution and would be found either on the present surface or impregnating the clay beds overlying the gaylussite. Neither is the case. The surface salinity of the basin is inconsiderable, and only two thin strata of the superposed clays carry noticeable amounts of salt, 195 to 232 ft., and 682 to 684 ft. A dried sample of the former, from 196 ft., contained 3.73% of water soluble materials, mostly sodium chloride and carbonate. A sample of the lower stratum, from 683 ft., contained 6.99% of water soluble material, mostly sodium chloride and sulphate.

Position of the Soluble Salts

In my opinion the facts are better explained by the hypothesis that the lake went completely or nearly to dryness. The more soluble salts would then be deposited above the gaylussite and probably over a more restricted area in the deepest depression. The failure to find them in the present drill-hole must be assumed due to the hole having been beyond the edge of this area. The gaylussite may have a much wider extent than the soluble salt bed overlying it. It is expected that later exploration work will either prove or disprove this.

On these assumptions, I am strongly inclined to regard the light colored clays between 556 and 718 ft. as the product of *playa* conditions following the complete desiccation of the lake. It is not impossible that the slightly saline stratum of 682 ft. may be an outlier of the main soluble salt body. The superposed black and gray clays, calcite-cemented strata, etc., are probably the record of a series of shallow and transient lakes subsequent to the greater lake which deposited the gaylussite, none of which minor lakes lasted long enough to produce any important chemical deposit. It is apparently only recently that this succession of transient lakes has given way to *playa* conditions and to intenser desiccation. Only the superficial 21½ ft. of the record is the product of the present conditions. It is quite possible, however, that short desiccation periods, similar to that now existing, have broken occasionally the succession of transient lakes and are recorded in the light colored clays encountered at 169, 306, and 463 ft. The slightly salty bed at 195 ft. may well represent a minor saline bed corresponding to one of the periods of desiccation.

Practically, the problem has now become one of finding the bed of soluble salts believed to overlie the gaylussite and which it is hoped may contain potash or other valuable salines. It is believed that the gaylussite horizon will furnish a datum plane which will make this possible and further holes are to be drilled immediately in order to obtain further data on the subject.

³Gaylussite is Na₂CO₃, CaCO₃, and 5H₂O; or sodium carbonate 35.81%, calcium carbonate 33.78%, and water 30.41%. My field identification of the gaylussite has been confirmed by J. Claude Jones.

Rock-Drill Testing at the North Star

By ROBERT H. BEDFORD and WILLIAM HAGUE

*The following article, describing efforts made to throw light on some of the dark spots connected with rock-drills and drilling, may prove interesting to those with whom the drilling problem is relatively important. At the North Star mine, Grass Valley, California, where these tests have been carried on, the ore is a narrow vein of quartz between walls of tough diabase in the upper, and no less tough granodiorite in the lower levels. The amount expended last year at this mine upon drilling, namely, for labor, power, repairs, lubricants, hose, and tool sharpening, was 20% of all outlays made. It is,

expends its energy in distending the diaphragm. The number and magnitude of these movements of the diaphragm, when suitably recorded, give a graph of the work done by a drill. The magnitude of each diaphragm movement is measured by a lever, so arranged as to record the displacement in an amplified form upon a strip of paper fastened to the periphery of a revolving drum. The graph so obtained, in addition to showing the number of blows per minute and the strength of each blow, shows any abnormal action of the drill. Results obtained with this crude apparatus were encouraging enough to warrant the

FIG. 2. TESTING MACHINE, WITH DRILL IN PLACE FOR TESTING.

therefore, of the utmost importance that the drills shall be kept in the best repair. The work of collecting details of drill-repair data started about two years ago. Early in the investigation it was found that drills which sounded all right when run against a block in the repair shop, frequently did but poor work underground. A great part of the loss in the mine was directly due to inferior condition of machines. There was needed some testing device which would give reliable information concerning the condition of a drill. W. D. Paynter, the 'drill doctor,' accordingly set himself to the task of devising such a machine.

The First Tester

The tester as originally constructed consisted of a plunger, cylinder, and diaphragm, the system being filled with oil. This is shown in Fig. 1.

The blow of the drill, through the plunger and oil,

*Acknowledgment is also given to the engineering staff of the North Star Mines.

building of a more elaborate and precise machine, the essential features of which have been patented by Mr. Paynter. This machine is able to test both air-feed stopers and reciprocating drills.

FIG. 1. DIAGRAMMATIC SKETCH, SHOWING ESSENTIALS OF TESTER.

Fig. 2 is a half-tone of the perfected machine, with a feed-screw machine in place to be tested.

Fig. 3 is the card of an air-feed stoper, No. 205.

This card was obtained in the following manner. The drum was revolved with no pressure on the system, the resultant trace is marked 'O air pressure.' Air was then admitted to the feed barrel and the drum revolved to give the trace marked 'feed barrel pressure.' With the drum revolving, the drill was started, giving the trace marked *A B C*, etc. The length of the line *A B* represents the magnitude of the kinetic energy of the blow delivered by the hammer. The reaction of the diaphragm in assuming its normal position is shown by the line *B C*. That the strength of the blow might be given in foot pounds, the tester was calibrated by means of a pendulum.

Fig. 4 is a card obtained from another machine of the same type but showing a small intermediate 'reactionary' blow, which has not as yet been explained. The drilling speed in hard rock should be compared to that given with Fig. 5.

Fig. 5 is a card of a machine in poor repair. It is of interest because it plainly shows a great departure from the graphs obtained from good machines of which Fig. 3 and 4 are examples. The great varia-

Table II shows the effect of various gauge pressures upon drilling speed in hard rock.

TABLE II					
Machine.	Gauge pressure ..	Blows per min....	Ft.-lb. per blow..	Ft. drilled per minute	Remarks.
No. 501	95	1210	39	0.36	Sharp steel.
.....	80	1170	34	0.34	
.....	70	1115	27	0.19	
No. 501	90	1200	38	0.26	Same steel as used in first test.
.....	80	1170	34	0.23	
.....	70	1115	27	0.14	
No. 201	95	1190	39	0.20	
.....	80	1150	34	0.20	
.....	70	1100	27	0.15	

In this table the blows per minute and the foot-pounds per blow at the various pressures are taken from curves plotted from the results of a number of tests made on machines of this type of construction.

FIG. 3. No. 205. AIR PRESSURE, 100 LB. BLOWS PER MINUTE, 1284. FOOT-POUNDS PER BLOW, 50.

tion in the actual drilling speed obtained by the machines shown in Fig. 4 and 5 in hard rock confirms what the tester indicates by the relative strength of blow.

Below are given in tabulated form the results of

From these results it appears that the drilling speed in this particular rock, and for this particular type of machine, depends largely upon the strength of the blow, within certain limits. The data are insufficient as yet to say more on the subject. In gen-

FIG. 4. No. 217. AIR PRESSURE, 96 LB. BLOWS PER MINUTE, 1260. FOOT-POUNDS PER BLOW, 40. DRILLING SPEED IN HARD ROCK, 105 FT. PER MINUTE AT 84 LB. PRESSURE.

tests on various machines. Unless otherwise stated, the machines tested are air-feed stopers of various construction.

TABLE I.—MACHINE No. 85,042

Gauge.	Blows per min.	Ft.-lb. per blow.
98	2280	29
90	2244	27
85	2208	25
74	2100	21
66	2016	20

It should be noted that the strength of blow seems to be more affected than the number of blows by the gauge pressure. Thus, in this instance, a 32% drop in pressure caused a 31% drop in the strength of blow, but only a 12% drop in the blows per minute. This has been the case with every type of machine so far tested.

eral this table confirms the results shown in Fig. 4 and 5.

Losses Due to Defects

The following tests show what loss may be caused in drilling speed by various defects in machines. Drill No. 516 was tested to find the effect of different conditions of feed packing leather.

Packing.	Gauge.	Blows per min.	Ft.-lb. per blow.
New	95	1356	44
Old	95	1332	39
Damaged	95	1296	34

Drills No. 507 and No. 09152, the latter a feed-screw machine, which had been reported from underground as being in 'good shape,' but unable to do satisfactory work, were tested before and after equipping with new cylinders. Both these machines

were reported as 'doing well' when again used in the mine. It should be noted that the blows per minute vary but little.

Machine.	Cylinder.	Gauge.	Blows per min.	Ft.-lb. per blow.
No. 507	old	98	1212	21
.....	new	95	1176	36
No. 09152	old	95	1248	16
.....	new	97	1224	36

As only one test was made to find the effect of various lubricants upon a new machine, the following figures are interesting, but not conclusive. A worn cylinder might give less pronounced differences.

Lubricant.	Gauge.	Blows per mln.	Ft.-lb. per blow.
Heavy	95	1116	25
Medium	95	1212	34
Light	95	1224	38

The statement is frequently made that excessive

Zorritos property is now producing in excess of 15,000 metric tons of crude oil annually, and the Lobitos field yields about 65,000 tons. The Talara, Negritos, and La Brea regions, worked by the London & Pacific and the Lagunitas companies, are producing between 120,000 and 130,000 tons. The chief markets at present for this oil are in Peru, Chile, and California, but with the opening of the Panama canal route, oil-tank steamers will undoubtedly pass through from the West Coast fields to the great consuming centres on the Atlantic seaboard.

The above companies are doing good work, as also is a recently formed company for the development of an important area adjacent to the Port of Bocapan, situated between Zorritos and Lobitos. This undertaking, known as the Bocapan Oilfields, Ltd., registered in Callao, consists of a property of some 900 *perlenencias* in a well studied area, more or less divided between Tertiary and post-Tertiary strata. Plant of modern type has been purchased

FIG. 5. No. 227. AIR PRESSURE, 84 LB. BLOWS PER MINUTE, 1272. AVERAGE FOOT-POUNDS PER BLOW, 15. DRILLING SPEED IN HARD ROCK, 0.05 FT. PER MINUTE AT 84 LB. PRESSURE.

air consumption indicates that a drill is in bad condition. From a large number of tests, machines of type No. 200 and No. 500 have been found to have an average air consumption of 75 to 80 cu. ft. free air per minute at 90 lb. gauge pressure. A test of a machine of this type using 90 cu. ft. of free air at the same pressure, gave 1296 blows per minute and 43 ft.-lb. per blow. From this it would seem that increased air consumption does not necessarily indicate that a machine will do poor work.

As a further example of the usefulness of the tester, this instance is cited. Four new valves were obtained from the manufacturers and were placed in machines. The tester showed that one failed to meet the standard set. Upon investigating, a piece of steel cutting was found concealed in one of the ports. This had throttled the air sufficiently to reduce the strength of blow about 35 per cent.

Although many tests have already been made, the data are by no means complete. We believe, however, it has been shown that by means of this device it is possible to set a standard which all machines must attain before leaving the shop, thereby facilitating the problem of drill maintenance. No figure in dollars can at present be given for the saving effected; but it may be stated that complaints from the mine about the condition of machines have been materially reduced.

Oil Production in Peru

*Along the north coast the following oil companies have been in operation for some time: The Lobitos Oilfields, Ltd., the Zorritos establishment of Faustino G. Piaggio & Co., Ltd., the London & Pacific Petroleum Co., Ltd., the Lagunitas Oil Co., and more recently the Bayovar Oil Development Co., Ltd. The

for working this property, and competent management has been engaged.

Costs at the Lake View & Star Mines

During its fiscal year, these properties produced 212,606 tons of ore, which was treated at the following cost:

COST PER TON	
Mining:	Milling:
Development\$0.50	Rock-crusher\$0.05
Breaking ore 0.97	Ore transport 0.07
Filling stopes 0.09	Stamping 0.35
Tramming and hoisting 0.58	Concentrating 0.14
Total mining\$2.14	Roasting concentrate. 0.11
	Filter-pressing 0.26
	Precipitation, clean-up 0.06
Cyaniding concentrate.\$0.06	Disposal of residue.. 0.10
Fine grinding concentrate 0.04	Total milling.....\$2.28
Fine grinding sand.... 0.35	
Preliminary grinding.. 0.17	General expenses 0.22
Agitation 0.52	Bullion charges 0.04
	Total working costs..\$4.68

The Lake View and Star mines are about a half-mile apart, and ore is taken to the mill on the former property by a narrow-gage steam locomotive and 3-ton cars. It is then dumped into a storage-bin or pass, and hoisted up the Lake View shaft. With ore from the latter, the whole product is broken by a large jaw-crusher and transported to the mill-bins by belt conveyor. There are 75 stamps at work, crushing ore through a coarse screen, the pulp being further reduced in Freeman pans, one for each battery of five stamps. After agitation, it is filter-pressed, precipitation of gold being by zinc shaving. The concentrate is roasted in Edwards furnaces, ground and amalgamated in pans, agitated, and filter-pressed.

*Abstract from Peru Today.

The Witwatersrand Gold Industry in 1912

By W. L. HONNOLD

*In the light of data now available for the past year it is clear that, taken as a whole, the mines of the Rand have made notable advancement. This is true in respect to both operation and intrinsic soundness, as well as the financial position generally.

A total of 25,486,361 tons was milled by about 60 producing companies, as against 23,888,258 tons during the previous year. The yield in gold amounted to £37,182,795, equivalent to 29s. per ton, which was 1s. 1d. per ton better than for 1911. The gold won was, therefore, 10.8% greater, although the scale of operations increased by only 6.7%. Explanation lies partly in the fact that for the previous year the unit recovery was abnormally reduced, owing to several companies mining an unnecessary proportion of unprofitable ore. Comparison is further complicated by the knowledge that in both years several companies, for good reasons, worked somewhat above the average grade of their ore reserves.

Average Working Cost

The average working cost advanced from 18s. to 18s. 6d. This apparent advance should not be taken too literally, since, to some extent, it was due to the fact that the figure for 1911 was unduly low because of the mistaken policy of mining unprofitable ore, referred to in the preceding paragraph. Apart from this consideration there were certain factors which undoubtedly affected costs unfavorably. Chief among these may be mentioned the increase in cost of native recruiting and higher wages. The high cost of securing labor has now been checked by the formation of the Native Labor Corporation, which will deal with the matter coöperatively and correct in some measure the past disadvantages of competition. Costs were also adversely influenced by increased inefficiency of white labor, brought about by the eight-hour law, more exacting government regulations, and the expenditure called for in consequence of legislation for the compensation of miners suffering from phthisis. The last charge will be largely eliminated by concerted application of preventive measures, more particularly the maintenance of a moist atmosphere throughout the mines by liberal spraying. In considering working costs, it has also to be borne in mind that in 1912, as in the preceding year, there was a disposition in many instances to charge directly to working accounts extraordinary items which, if money could have been raised as freely as in the past, would have been dealt with as capital expenditure.

The working profit totaled £12,678,095 as compared with £11,415,861 for 1911, a gain of slightly over 11%. The per ton figures for the two years were 10s. and 9s. 7d. respectively.

In the matter of dividends the showing is outwardly not so satisfactory. There was an increase of £189,908 in the aggregate distribution, making

the total for the year £7,952,994, but the per ton declarations averaged only 6s. 3d. as against 6s. 6d. for the previous year. The explanation lies chiefly in that the money markets were unfavorable to the provision of additional working capital. For this reason it was necessary, as in the year before, to appropriate large amounts to cover extraordinary expenditure in connection with additions and alterations, both underground and at the surface. These changes had to be undertaken at this time, more particularly in connection with the recently merged properties, and under more propitious monetary circumstances would have been charged to capital account. This point will perhaps be clearer if the following per ton figures are considered:

	Working profit.	Distrib- uted.	Undistrib- uted.
1910	10s. 6d.	8s. 1d.	2s. 5d.
1911	9s. 7d.	6s. 6d.	3s. 1d.
1912	10s. 0d.	6s. 3d.	3s. 9d.

The tendency shown by this comparison would be cause for uneasiness were it not that the special improvements to which it is due are either completed or nearing completion. It has, however, to be borne in mind that, as a result of the hopeful feeling which prevailed in 1910, certain mines overreached themselves and made a better showing than was warranted by their intrinsic position. Figures for that year consequently cannot be taken as an absolute basis of comparison, although in the aggregate they were not far out and may be again realized. One is forced to the conclusion, therefore, that the relatively poor showing of the last two years in the matter of dividends is not due to intrinsic deterioration, but to an enforced change in financial policy.

Working Profit v. Dividend

Whether and to what extent it may be possible and advisable to bring about a closer relationship between working profit and dividend than that shown above, is a question open to difference of opinion, but not so simple as has been suggested. If we take working cost as covering all head office, maintenance, and operating expenses, including the development called for by the equipment provided, then the remaining super-charges against working profit fall chiefly under the heading of interest and redemption of loans, profits tax, and capital expenditure. It would, of course, be possible to add to the published monthly and quarterly costs a fixed charge per ton under each of these three headings, or any others that might be called for. These fixed charges would be based on experience and probability and would be fairly reliable as to loans and profits tax, although in the latter case, owing to its determination being a matter of complex calculation by government officials at the close of the year, only an approximate figure could be used. The matter of capital expenditure, however, would present far more difficulty. As commonly interpreted, it embraces all the various and varying items of ex-

*Published by arrangement with the *Michigan College of Mines Quarterly*.

traordinary expenditure necessary to conform to engineering progress, meet the demands of expansion, and deal with both incidental and accidental exigencies of major importance. These items, obviously, cannot be charged directly to working costs without perversion of the comparative value of the latter and the consequent confusion of the shareholders. It is not surprising that directors and engineers hesitate to forecast expenditure when it includes such a variety of items. If a true approximation were attempted, those responsible would probably find themselves either trammelled by underestimates or criticized for misleading overestimates.

Financial Policy

In practice, the latter would probably be taken as the lesser of two evils and generous provision would be made against contingencies, a course hardly favorable to economy. It may be urged that any resulting surplus could be carried forward or credited to general revenue and expenditure. But this is equivalent to abandonment of the advantage aimed at; for the surplus might equal the margin of uncertainty under the present policy. Even if it were possible to forecast the expenditure with approximate accuracy, and this forecast were embodied in the monthly and quarterly reports, the showing would still be open to misconstruction owing to uncertainty as to the financial policy that might be called for at the close of the year, more particularly as to the matter of balance forward. Furthermore, the financial policy of a company is open to modification in accordance with market conditions, or other circumstances, and there are a number of companies which at a favorable moment may, by new share issues or otherwise, materially alter their position and thus make available for distribution amounts that have now to be apportioned to capital expenditure. Enough has been said to show that the question is not so simple as has been implied by some critics. The prevailing custom admittedly results in interim reports which do not directly reflect the dividend position. Such perfection, however, is not aimed at; it might be realized by some of the companies some of the time, but not by all of the companies all of the time, a consideration of special bearing where uniformity is as important an item as on the Rand.

Reports

All that is claimed for the monthly and quarterly reports as now published is that they provide confirmation or modification of certain comparative data, the dividend significance of which has been previously foreshadowed by precedent and prophecy with as much certainty as would probably result from a more ambitious attempt. Taken in this light, much can be said in their favor. It should, perhaps, be added that some critics have advocated going to the other extreme and publishing no interim reports whatever, their argument being that, apart from the fact that at best such publications may prove misleading in some degree, there is the practical consideration that they may lead to a somewhat costly struggle for regularity in matters essentially irregular.

Recent Position of Companies

With regard to the industry as a whole, it is doubtful if, taken from the standpoint of actual demonstration, it has ever shown greater soundness, that is, a more satisfactory correlation between salient factors. The financial position of the companies generally is unusually strong. Plants are in good condition and, where required, have been enlarged to meet the demands of expansion. Necessary underground haulageways and mechanical facilities have been provided to meet the requirements of increasing tonnage and greater tramping distance. Development is well advanced and there is apparently no material change in tenor. The native labor situation is probably more satisfactory than ever before, and is in the way of further improvement, partly through the better organization recently effected, and partly through the wider use of machine drills. In the latter connection, it is interesting to note that the number in use has increased by about 57% within the past two years, a total of 5634 drills now being employed. Unfortunately, the white labor position is not so satisfactory, this country, like most others, having now to contend against both shortage and inefficiency. This difficulty will probably disappear when it is recognized, as it inevitably must be sooner or later, that the existing prejudice against the employment of natives of superior capacity on certain so-called 'skilled labor' is unreasonable and inadvisable under the circumstances. The prospect in this connection, however, is too vague to be reckoned at present. Generally speaking, the mines are neither unduly pressed as to tonnage and grade, nor over-strained as to dividends. In fact, there is a reserve of strength in the working position that promises to find expression in a materially improved showing for the current year.

Gold in the World's Banks

The following table, dealing with this important subject, has recently been compiled by the London *Statist*, as shown in the following table:

Banks	1913	1912
Austria Hungary	£ 50,412,000	£ 52,067,000
Belgium	8,883,000	7,611,000
Denmark	4,483,000	4,344,000
England	38,493,000	41,510,000
France	132,641,000	130,440,000
Germany	53,977,000	44,395,000
Italy	50,463,000	46,084,000
Netherlands	13,451,000	12,033,000
Norway	2,349,000	2,035,000
Russia	161,101,000	150,498,000
Spain	18,216,000	17,034,000
Sweden	5,704,000	5,225,000
Switzerland	6,836,000	6,420,000
United States Treasury	256,954,000	247,330,000
United States national banks....	30,248,000	32,675,000
*Argentina	52,660,000	41,854,000
*Brazil	24,909,000	23,076,000
†India	25,664,000	21,620,000
Total	£937,444,000	£886,251,000
*Conversion offices.		
†Currency and gold standard reserves.		

To this should be added about £20,000,000 held by banks in Australasia.

SHEEP CREEK CAMP AND AERIAL TRAMWAY TO TUNNEL. MAIN ADIT TO PERSEVERANCE MINE.

Preparatory Work of the Alaska Gold Mines Company

By GRANT H. TOD

The work being conducted by the Alaska Gold Mines Co., the holding company for the Alaska Gastineau Mining Co., is of great interest to the mining public, and a brief outline of the general situation should be opportune. The ground now being developed comprises a mineral district from 70 to 400 ft. wide, with an approximate length of three miles. The ore in this zone averages from \$1.50 to \$2 per ton, with an estimated recovery of from \$1.25 to \$1.50 per ton. The margin of profit is estimated to be from 50 to 75c. per ton milled. This grade of ore will necessitate working a large tonnage, and for that reason a little over two years ago the Alaska Gastineau Mining Co., being satisfied with the results of development work, commenced operations on a large scale. The first work to be done was the driving of adits to cut the orebodies at depth and afford transportation facilities for the ore from the mine to the Gastineau channel. The millsite and railroad con-

nections with these adits can be seen close to Juneau, and have been so arranged as to facilitate the handling of ore.

Mine Development

Plans being carried out at this time are as follows: The Perseverance claim, in the Silver Bow basin, being developed by means of raises, shafts, and drifts, has resulted in the opening of some large stopes. The building of permanent houses to replace the construction camp is now well under way. Machinery and railroad facilities are being rapidly installed which will handle a daily output of 10,000 tons. The plan of development is to be so arranged, owing to recent discoveries of new orebodies in the mines, that this output can be increased to 20,000 tons per day. At the Perseverance mines, H. J. Jackson, the superintendent, is pushing development work. The main vertical raise, 940 ft. in height, has been enlarged to a 3-compartment shaft and is now being sunk to meet the main

SALMON CREEK CAMP AT DAMSITE. ALASKA GASTINEAU MINING COMPANY.

RESERVOIR-SITE ON SALMON CREEK,

adit from the Sheep creek side, on the Gastineau channel.

One feature of interest is the fact that practically all the metal content of the ore in the Gastineau properties is contained in the large quartz lenses that make up about 50% or over of the entire ore zone. This permits of an easy mechanical sorting process at the mills, by using roughing tables as sorters. The rest of the ore zone, being slate and of little value, is easily sloughed off, after the first grinding, and does not need to enter into any future treatment of the ore. This places an entirely new face on the possibility of treating \$1.75 grade of ore.

Ore Transport, Power, and Mill Construction

At Sheep creek, south of Juneau, on the Gastineau channel, a large tract of land was obtained on which will be built the mill, machine-shops, boarding and bunk-houses, warehouse, and other buildings. The first unit of the plant is to have a capacity of 6000 tons per day.

An electric railroad is being built to connect the millsite with the Perseverance mine, three miles distant. Two miles of this distance will be through an 8 by 10-ft. tunnel, which is now being driven

in hard slate at a splendid rate of advance. During the month of June, 570 ft. was driven, and on some days during this month a rate of 1 ft. per hour was maintained. The ground was stiff, requiring 24 holes to be drilled to the round. A good indication of the splendid system with which this work is being conducted is the fact that, although the tunnel has now advanced over a mile, the miners are back in the face of the tunnel rigging up the top bar 14 minutes after blasting. The tunnel is being driven on the strike of the lode and will connect with the shaft of the Perseverance mine, and will cut the ore zone at a depth of 2300 feet.

At Salmon creek, about four miles north of Juneau, a dam of the variable radius arch type is under construction, having a height of 165 ft., and approximately 700 ft. long on the crest. This storage system will furnish continuous electric power of about 6000 hp. for use at both mines and mills. It is expected that the actual pouring of concrete will commence late in July. When complete the dam will contain about 60,000 cu. yd. of concrete, requiring about 15,000 tons of cement. The handling of this tonnage of cement is conducted most ingeniously. The cement is loaded on covered cars and carried in them on barges to Salmon creek

BUNK-HOUSES, DOCK, AND TEMPORARY SHOPS. MILLSITE BEING CLEARED. SHEEP CREEK.

dock. Here they are hoisted by cable tram to the railroad at an elevation of 300 ft. Then comes an uphill pull for 4 miles to another cable tram, where the cars are pulled to the damsite proper, and the cement handled for the first time after being unloaded from aboard ship in the Gastineau channel. The dockage system at Salmon creek is most ingenious, enabling a barge to land at any stage of the tide. An apron car or lift, designed by J. R. Whipper of the Gastineau company, is in use. This is quite a feat owing to the tremendous differences in tide-level at this point.

Regarding the operation of the plant, it is the present intention of the management to have the first unit of the mill in operation by January 1, 1914, and it is pleasing to note that development work is well in advance of the plans contemplated a year ago.

A complete experimental mill of 100 tons per day capacity is in operation under B. E. V. Daveler. This mill is practically a test mill for the large plant now under construction.

During the present construction period the Alaska Gastineau company is employing about 1000 men, the payroll for January being over \$90,000. With the first unit in operation, the Company expects to employ about 1500 men. The general outlook would indicate that the Alaska Gastineau will be a large producer.

Cyanide From Residue of Sugar-Mills

By C. A. BROWNE

*Germany has made the greatest advancement in this regard. Of a total production of 400,000 tons of beet molasses in this country, about 55% is desaccharified for sugar production, about 30% is used as cattle food, about 10% is fermented into alcohol, and the remaining 5% is utilized in miscellaneous ways. Among the last may be mentioned the use of molasses for manufacturing dye stuffs, shoe blacking, yeast, molds and briquettes, and numerous other commodities.

The residues from the desaccharification factories, best known under its German name of molasses *schlempe*, has been a subject of special study from the standpoint of utilization. From 1000 kg. of beet molasses are obtained about 350 kg. of concentrated *schlempe*, containing about 30% of mineral matter, mostly potash salts, some 20% or more of nitrogenous substances, and a remainder of acids, gums, caramelization products, and other organic residues.

Molasses *schlempe* contains 12 to 15% of potassium and 4% or more of nitrogen, and its conversion into derivatives of these elements constitutes at present the chief method of utilization. The *schlempe* is first heated in retorts, by which means it is decomposed into a mixture of volatile products consisting of carbon dioxide, carbon monoxide, hydrogen, nitrogen, methane, ammonia, methyl amine, methyl alcohol, water, and other substances. The volatile decomposition products escape from the retorts at a temperature of about 400°C. and are led through a system of tubes heated to a temperature of about

1000°C. The effect of this heating is to convert the volatile nitrogenous compounds into ammonium cyanide, the gas after cyanization containing about 7% NH_3 and 7% HCN . After leaving the hot tubes, the gases, which are always kept under reduced pressure, are cooled, freed from tar, and then washed over sulphuric acid to break up the ammonium cyanide, the ammonium sulphate, which is formed, being recovered. The hydrocyanic acid is then absorbed in water, and the residue of combustible gases is led back to the furnaces for heating the retorts. The hydrocyanic acid is then distilled, and absorbed in sodium hydroxide; the solution of the latter, after evaporating and crystallizing, yields solid sodium cyanide.

By the above method, about three-fourths of the nitrogen in molasses *schlempe* is recovered as ammonium sulphate and sodium cyanide, the remaining one-fourth escaping as gaseous nitrogen. A small amount of pyridine is also obtained by this process, in connection with the ammonia. The residue of mineral matter in the retorts, after distilling the *schlempe*, is worked up into potash, of which some 15,000 tons is made annually in Germany from this source.

Two factories in Germany produce annually, by the process of distillation described, about 5000 tons of ammonium sulphate and 5000 tons of sodium cyanide, with a commercial value of about \$1,750,000. The sodium cyanide thus manufactured is nearly all exported to the Transvaal, where it is used for extracting gold by the well known cyanide process.

Chemists in Germany are making further efforts toward improving the utilization of molasses *schlempe*. By the present methods of distillation, about one-fourth of the nitrogen is lost, and this is wasteful from the standpoint of highest economy. It has been felt by some chemists that efforts should be made toward removing some of the valuable organic constituents of the *schlempe* before making the distillation.

Japanese Oil Production

The Nippon and Hoden Petroleum companies imported rotary boring machines from the United States last year and have been engaged in the boring of oil wells. Since then the yield of petroleum in Japan has greatly increased. Until last spring the average output of petroleum was about 4000 bbl. per day, or about 1,430,000 bbl. per year. This output has recently increased to about 5700 bbl. per day or about 1,900,000 bbl. per year. Those engaged in the petroleum industry are now planning to expand their business by employing the rotary boring machine, and it is expected that the yield of petroleum will be considerably increased within a few years, so that most of the imports from abroad may be checked. At present about 2,660,000 bbl. of petroleum is yearly imported from Russia, the United States, and other foreign countries.

Aluminum bus-bars in place of the copper equivalent, for switchboards, have shown a higher efficiency, and a minimum saving of 25% in price is effected, according to the British Aluminum Company.

*Abstract from Columbia School of Mines Quarterly.

Geology of the Kalgoorlie Goldfield—III

By MALCOLM MACLAREN and J. ALLAN THOMSON

The rocks within the Kalgoorlie auriferous belt are shown in the following table, in which is also indicated the influence of each on auriferous deposition. Only the solid geology is considered, and recent surface deposits are neglected. The rocks are shown in order of increasing age from top to bottom of the table.

It is impossible to determine at any rate with the data at hand, the relative ages of the various members of the Younger Greenstones. To this generalization there is one marked exception, for felspar (albite) porphyry dikes are found ramifying through most of the others. They are, therefore, clearly the youngest members of the group. For

1. Albite porphyry		Barren
2. Porphyrite		Barren
Younger Greenstones	{ 3. Ultra-basic rocks; serpentine, hornblende rock, talc-schist, magnesite rock. 4. The Kalgoorlie quartz-dolerite dike	{ Barren
		{ Highly auriferous
5. Sedimentary series: shale, micaceous schist sandstone		Barren
Older Greenstones	{ 6. Fine grained amphibolite and calc-schist	Barren
		{ Normally barren but occasionally auriferous when near contact with quartz-dolerite greenstone of the Boulder type.

Younger Greenstones

The forces that, acting at the surface, folded the rocks as above indicated, also exercised the pressure at great depths, on the magmas, molten, or potentially so, that are assumed to exist beneath the solid crust, with the result that molten igneous rock was forced toward the surface along the foliation planes of the Older Greenstones, giving rise to the various rocks that are here grouped together under the title of Younger Greenstones. They have a great range in character and include ultra-basic rocks as peridotite as well as felspar-porphyry rock high up in the scale of acidity. According to modern views, these various rocks may well be regarded as differentiates discharged from a single magma during the course of its cooling. The assumption is open to objection and is here advanced merely as being a helpful conception in grasping the internal relations of these Younger Greenstones. The various members of this series in increasing percentage of silica (acidity) were: peridotite, pyroxenite, hornblende-dolerite, dolerite, gabbro, quartz-dolerite, with their associated rocks, porphyrite, and felspar (albite) porphyry. It is to be remembered that the original nature of the individual members of the above series is not always clear; peridotite has given place to serpentine, talc-schist, and a coarse carbonate rock; and both pyroxenite and hornblende-dolerite have yielded amphibolites, the rock derived from the latter being 'lustre-mottled.' Gabbro and dolerite have changed to epidiorite, while the quartz-dolerite has suffered various changes. The more acid porphyrite and felspar porphyry alone remain unchanged.

Of the Younger Greenstones, those occurring in the immediate neighborhood of Kalgoorlie have naturally received the closest attention, though somewhat similar rocks are found throughout the region. A large area of ultra-basic rocks (serpentine, etc.) lies to the east of Bulong and stretches away to the north and to the south of that town. It has yielded traces of copper deposits, but its gold occurrences have so far proved insignificant.

the other, it is assumed that gabbro, dolerite, and quartz-dolerite are fairly representative of the original magma and that they were first extrusions from the magma. With further cooling and pressure peridotite and pyroxenite were expressed from the main mass and these were followed by a more acid product of cooling (porphyrite). The internal relations of these rocks appear, however, to have no economic significance and no bearing on the origin and filling of the auriferous lodes and need not be further discussed. But gold has a peculiar, and as yet unexplained, affinity for one member of this series, the quartz-dolerite. Therein lies the importance of the whole series. It is abundantly clear from the physical characters of the members of the Younger Greenstones series that they solidified slowly and under considerable pressure. They were then far from the then existing surface; in the course of geological ages many hundreds of feet of solid rock have been removed from above them by the agents of denudation.

Differentiation Series

At this stage in the history there was a broad area of crushed, upturned, and denuded igneous schists and sedimentary sandstones, grits, and conglomerates intruded, along their foliation planes, generally N.N.W.-S.S.E. by broad dikes and masses (batholiths) of ultra-basic, basic, intermediate, and slightly acid rocks (Younger Greenstones), all the latter being presumably members of a 'differentiation series' from a common magma. The surface was possibly partly covered with lavas and ashes ejected from volcanic vents situated on the track of those dikes that reached to that height.

There now came the last of the great internal modifications to be undergone by the rock complex above outlined, that caused by the mighty intrusions of granite that form so large a portion of the present surface of Western Australia. These were apparently not accompanied by violent compression of the greenstones; they rose, so far as can be seen, beneath great anticlines of the greenstones, probably lifting the anticlinal crest a little higher.

It is not probable that there was much 'stoping' of the overlying rock; neither the margins nor the surfaces of any granitic areas that have been examined show inclusions of greenstone or evidences of the local cooling of the granitic magma that would accompany such 'stoping'. The long narrow greenstone bands throughout Western Australia, therefore, in all probability represent the bottoms of the great folds into which the Older Greenstones were thrown prior to the slow upward welling of the broad granitic magmas.

There were naturally enough intrusions from the main granite mass along lines of weakness in the greenstones. These are aplite, pegmatite, and granite-porphyry with a few miles of the margins of the granite, but farther away in the greenstone tongues from the granite are few and small, and are represented by thin quartz-porphyry dikes.

The Older Greenstones

In the description of these rocks, it is most convenient to commence with the oldest. These are the fine-grained amphibolites and calc-schist of the Older Greenstones. Their geological relations have been sketched in the preceding article. They are assumed to represent ancient lavas and tuffs that were probably andesitic to basaltic in character. This rock forms a single broad belt, nearly two miles wide, striking N.N.W. and S.S.E. The Kalgoorlie dike to the south is intrusive in the middle of the belt, while its two northward tongues lie, one near the western margin and the other near the eastern margin of the Older Greenstone belt.

In hand specimens the fine-grained amphibolite shows no structure. Its color varies from bluish green through greenish gray to gray. In the lighter-colored specimens, an irregular, close network of minute quartz veins is very characteristic. The rock is only faintly schistose, and this character is in any case only developed on weathering. It does contain bands of fissile sericite (white mica) schist, but these are not inherent to the mass of the rock and are developed only along later and local shearing planes. Two main types of rock occur in the amphibolite series: The first consists essentially of an aggregate of feathery needles of amphibolite with zoisite, epidote, quartz, and chlorite; the second of lathe-shaped feldspar in a hornblende felt. These characters are microscopic and cannot be made out with the naked eye. The distinctly amphibolitic portion of the belt lies in the northeastern portion of the area. The characters of the western portion are hardly known, since there are no workings in it, and it is for the most part, especially in the township of Kalgoorlie, completely covered by detrital products.

Near the large mines in the southeastern part the amphibolite loses its green color and becomes slaty gray to white, a change due to the removal of chlorite by vein-waters radiating outward from fissures into the mass of the rock. This dike has been provisionally termed 'calc-schist', though the schistosity is not strongly marked. The first term of the name indicates the predominance in the rock of calcite and allied carbonates. All hornblende, and even all chlorite derived from hornblende, has been

leached away by slow-moving waters, and these rocks are now merely aggregates of carbonates (dolomite, siderite, calcite, and intermediate forms), quartz, and sericite, through which magnetite and pyrite are impregnated. When these rocks become schistose there is a correspondingly greater development of sericite mica. Occasionally the carbonate is segregated into large rhombohedra of calcite, and in this case a considerable amount of chlorite is left unaltered. This calcite-chlorite rock is typical of a large area in the north of the Kalgoorlie Amalgamated leases of the Oroya Links, Limited.

The fine-grained amphibolites are barren. In no case in Western Australia has a gold mine of any importance been developed in them. The calc-schist rock is also normally barren, but in two cases at Kalgoorlie they have been known to contain important orebodies. These are the famous Oroya Brownhill 'pipe' and the Eclipse lode, belonging to the Oroya Links, Ltd. In the first case, the Oroya Brownhill 'pipe' lies along the contact of the Kalgoorlie quartz-dolerite dike, and in the second the ore of the Eclipse lode has probably traveled in solution from the quartz-dolerite northward along the track of the Lake View lode fissure, the strongest in Kalgoorlie, and has been deposited in the Eclipse ground by the local influence of a small albite-porphyry dike which there crosses the Lake View lode channel. Other small deposits are known in this rock, but as they are confined to the oxidized zone, they are regarded as merely local secondary surface deposits, not genetically connected with calc-schist, and indeed deposited there despite rather than by virtue of the enclosing rock.

Sedimentary Series

Within the area described, sedimentary rocks have but a small development. They occur on the eastern side of the fine-grained amphibolite belt, and form the western margin of a broad belt of silicious shales, schists, and fine grained schisted quartzite that underlies the valley lying east of Kalgoorlie. They are easily eroded and sink to form the valleys of the regions. Definite information regarding them is, therefore, difficult to obtain. As a matter of fact, they are exposed at one spot only, the old Phoenix brick pits, northeast of Hannan's brewery. Here they are fine grained recemented quartzites whose bedding (or perhaps foliation) planes strike north 30° west, and whose dip is steep to the southwest. They are grouped together with the Older Greenstones, and have, like them, suffered the same folding and crushing described in the previous chapter. Within the area mapped they are not known to carry any auriferous veins, and from experience elsewhere they may be regarded as inherently barren.

Newer Intrusive Rock

Both the Older Greenstones and the sedimentary series were subjected to pressure from east-north, east-west, and south-west, and from being horizontal they were first compressed into low broad swelling waves. With increase of pressure the crests of the waves were brought closer and closer until they finally touched (isoclinal folds), so that in the end

the originally horizontal strata were highly inclined, and all dipped the same way, to the westward. Their strike, in obedience to the pressure, was of necessity N.N.W. and S.S.E.

The same earth pressure was exercised at a depth of, say, 10 to 15 miles, which when the diameter of the earth is considered, may be regarded as at the earth's surface. At this depth, however, it operated on a fluid, or potentially fluid, igneous magma whose only channels of escape from compression were toward the surface. And so the less viscous portions of the magma were pressed upward through fissures in the overlying solid earth crust. Passing into that portion of the surface composed of the Older Greenstones and sedimentary rocks described above, they found their easiest passages along the foliation planes of the older rocks. These have a strike N.N.W. and S.S.E., and dip westward. The numerous dikes of igneous rock forcing their way along the foliation planes and solidifying there have, therefore, of necessity the same general strike and dip. The recognition of the strike and dip of these dikes is of prime economic importance, since they contain all or nearly all the auriferous deposits of Western Australia and since the life of a mine depends on its possession of as large a solid block of the auriferous dike rock as possible. This point is made clear on studying the transverse sections of the Kalgoorlie goldfields and comparing the respective quantities of the auriferous dike rock possessed by, say, the Associated Gold Mines and the Ivanhoe Gold Corporation, Limited.

The Kalgoorlie Dike

Locally one dike and its northward extension is especially important. This is here termed the 'Kalgoorlie dike.' It is composed of 3 members: (1) quartz-dolerite greenstone (Boulder type); (2) quartz-dolerite greenstone (North End type); (3) quartz-dolerite amphibolite. It is, however, to be clearly understood that there is no great petrological differences between these three rock types, and that they represent not original differences, but rather local variations due to difference in pressure or more probably to rate of cooling of the original magma, which was essentially a quartz-dolerite. The original magma, when forced into the position now occupied by the Kalgoorlie dike, was homogeneous. Since, however, this present survey is primarily economic, and as the slight variations noted above appear to exercise a potent influence on auriferous deposition, it has been considered necessary to adopt the foregoing classification.

The Kalgoorlie dike has in the south of the area an average breadth of a mile. With this breadth it rises from beneath the deposits of the slope toward Hannan's lake and strikes N.N.W. for a distance of nearly two miles, or to the North Kalgurli and Brownhill leases. Disregarding for the moment minor irregularities, it sends northward two long narrow tongues through the Older Greenstone. For convenience of description, the eastern tongue is termed the Brownhill branch, and the western the Hannan's branch. The Brownhill branch leaves the main dike near the old Trafalgar shaft and passes

beneath the Brownhill township to Parkeston township and so beyond the limits of the survey. In the far north it has narrowed to a few hundred feet. Its average thickness is less than a quarter of a mile. The western or Hannan's branch of the Kalgoorlie dike leaves the main body at the North Kalgurli and passes west of the Eclipse shaft through Maritana and Cassidy hills, thence through the Hannan's Reward leases (whence the name of the branch) through the Golden zone and New Reefers leases and beyond. Its outlines are irregular in horizontal section, but its average width may be stated as a little more than a quarter of a mile. It is narrow near its point of departure from the main body, but swells to its maximum width of half a mile in the neighborhood of the Golden Zone lease north of the Mt. Charlotte reservoir.

Quartz-dolerite Greenstone (Boulder type)

This is, both economically and petrologically, the most important rock type in Kalgoorlie, for it not only contains nearly all the important known ore-bodies, but it also represents most nearly in composition the general mass of the magma that welled up to form the Kalgoorlie dike. This rock when originally solidified is believed to have been one that might be termed indifferently quartz-dolerite, quartz-gabbro, or quartz-diabase. This apparent confusion is not entirely due to any inherent difficulty in determining the nature of the rock. The choice between the two first terms is merely a matter of structure, and the first has been selected as approaching more nearly to a correct name for the mass of the rock. A choice between quartz-dolerite and quartz-diabase is possible because of the confusion in petrological nomenclature owing to the rapid growth of the science; many pairs of terms are now engaged in a battle for existence, and it will be yet a generation before these struggles are ended. 'Quartz-dolerite' is selected in this place merely because it is believed that it will finally emerge as victor; it is conceded that most petrologists of an older school would prefer the term 'quartz-diabase.'

But the auriferous rock of the Kalgoorlie mines has not readily been recognized as a quartz-dolerite. During long years of subjection to pressure and to the action of slow-moving percolating waters, some of its original minerals have been decomposed and their place has been taken by others with a considerable rearrangement in the structure of the rock. It has not been found possible finally to determine the original character of the rock from a single specimen, and it is only after the consideration of several hundreds of rock slides that the character of the original rock has been reconstructed. The original rock contained a peculiar intergrowth of quartz and felspar, columnar crystals of a basic felspar, augite, probably hornblende, and a relatively small quantity of unimportant minerals. There now remains only the intergrowth of quartz and felspar; all the others have suffered a change. The basic felspar has been converted to albite, both augite and hornblende have been changed to chlorite, to which the dark green color of the freshest specimens ob-

tainable is due. It has therefore been necessary to indicate that the freshest rock now to be found is yet a much altered one; and this has been fulfilled by the selection of the term 'quartz-dolerite greenstone'; that is, a somewhat indefinite rock derived from quartz-dolerite and one that would fall into the old, useful, field group of greenstones.

The mapping of the distribution of this rock has proved to be the chief problem of the survey. From the north of the main mass, spring the two branches previously mentioned, but there is also another short tongue projecting northward to Block 45 of the Oroya Links, Ltd., lease. As shown by the underground contours this tongue rises rapidly to the surface from the south. In both the Hannan's and Brownhill branches of the Kalgoorlie dike the quartz-dolerite greenstone of the Boulder type soon gives place to either the North End type or to an amphibolite, both of which are unproductive. In all three tongues it would appear that the maximum breadth of quartz-dolerite greenstone is exposed at the surface, and that the tongues narrow in depth.

Description of the Quartz-Dolerite

The quartz-dolerite greenstone is normally a dark-green rock of medium texture, but it has also a wide variation both in color and in grain. The color is due to a green mineral, chlorite, which is decomposed by vein-waters. With the disappearance of chlorite the rock becomes lighter in color, until it finally reaches a dead white, which is the color of the then predominant carbonates, feldspar, mica, and quartz. In this case the iron of the chlorite forms pyrite with sulphur from the vein-waters, but in other cases the iron may be partly oxidized. The rock then assumes a pink color, which rapidly changes to red on exposed surfaces. In grain also the quartz-dolerite greenstone may vary from a coarse gabbroid rock to a fine grained dense mass. The aspect of the rock is generally porphyritic owing to the preservation, in the general process of alteration, of the outlines of the large columnar feldspars so characteristic of the ordinary diabasic structure. It is this porphyritic appearance, together with the destruction of the other original minerals, that has led Judd and others to describe the rock as a quartz-andesite. The most characteristic mineral in hand specimens, however, is leucoxene, a whitish to light yellow mineral arising from the decomposition of ilmenite. It is best seen on wetted surfaces and may always be recognized by its skeletal structure, which resembles a close network of superposed, unequal-sized triangles having often a common side. The lustre is occasionally slightly metallic and the mineral may then be mistaken for pyrite. A hard lens will, however, nearly always disclose the characteristic triangular skeleton. Quartz-blebs are numerous through the rock. These are black in color owing probably to the background of dark chlorite, and may then be mistaken, without a hand lens, for broken crystals of magnetite. The micro-pegmatitic structure (intergrowth of quartz and feldspar), the most characteristic feature of the rock, cannot be observed in hand specimens.

Changes in Color of the Rock

The most striking variation visible to the miner is the change in the rock from green to red or white noted above. The former rock is the 'diorite' of the miners, the latter 'granite' or 'porphyry.' The evidence from the mine workings confirms that of the microscope in the assumption that the latter is merely a bleached form of the quartz-dolerite greenstone, impregnated with lime, magnesia, and iron carbonates. The white or pink variety varies in width from an inch or even less on the wall of a fissure, to bands many feet wide. The extension of a white or pink band both in length and in depth is always erratic. The bands may be continuous for hundreds of feet in length or depth, or may cease suddenly at a 'head.' They are best developed at and near the intersection or junction of two strong lode-channels. While no general rule may be made out, they may be said to be better developed on the foot-wall side (in this case the east) of the fissures to which they owe their origin. To understand this distribution, it must be remembered that while foliation or crushing is more or less parallel to the walls of the Kalgoorlie dike (60 to 65° W.S.W.), the dip of the strong shear-zones in which the lodes are formed is on the whole nearly vertical. Vein solutions rising in the fissures will therefore find an easier passage up the open combs on the east than down the same combs on the west.

Color v. Mineral Deposits

Fortunately this alteration has no great bearing on the economic problem. It is true that a lode on passing from the normal quartz-dolerite greenstone into the white variety may spread the gold so widely that the lode channel ceases to yield payable (for example, the Australia east lode from 600 ft. L. to 1000 ft. L.), but on the other hand, an enrichment of the lode may take place in the white rock. When it is stated that the rich Tetley's, Kalgurli, and Hainault shoots all lie in this rock, it is clear that it exercises no detrimental effect on the formation of orebodies. As a matter of fact, the presence of much white or pink rock may be taken as evidence of the existence of strong lode-channels, since it has been formed from solutions passing along the same fissures in which afterward, or perhaps even at the same time, the telluride and sulphide ore was deposited.

The Bureau of Mines proposes to make tests to establish a list of electric switches permissible for use in mines where inflammable gas may be present. The conditions under which these tests will be made and the regulations governing the submission of switches for test will be published in a forthcoming bulletin.

Concrete work for the Panama canal locks is practically completed. On June 21 the total quantity laid was 4,471,463 cubic yards.

Rubies valued at \$17,000 were produced by washing 86,000 loads of ground at the Burma ruby mines, in June.

Operation of the West End Mill, Tonopah

By JAY A. CARPENTER

*While costs might be lower if the mill were situated at the mine, where certain expenses could be shared in common, they are at present at a figure that compares favorably with mills of an equal or greater tonnage. The extraction of silver and gold for the year, while nearly the average obtained, falls short of the best results in the district. During the first quarter of the year it was 88%, due to treating over \$17 ore, containing coarsely crystallized ruby silver, without concentrating. Unexpected mine developments giving this grade of ore after belt sorting for smelter shipments, caused prompt action to be taken in adding the concentration addition, the excavation for which was started May 20, and the unit completed and put in operation July 1, 1912. With the increased tonnage and improvements made during the past year, the current term should show a further decrease in costs and an increase in extraction.

Treatment Operations

Results may be stated as follows:

Ore treated, tons	44,756
Gold content, ounces	9,357
Silver content, ounces	93,337
Gross value of ore	\$764,854
Gross value per ton	\$17.09
Gross value recovered	\$690,932
Gross value per ton recovered	\$15.44
Gross value in tailing	\$73,922
Gross value per ton, tailing	\$1.65
Recovery before shipment, per cent.	90.3
Recovery after deducting transportation and treatment charges, per cent	88

The total recovery of metals was:

Gold, ounces	8,817
Silver, ounces	830,893
Gold extraction, per cent	94.24
Silver extraction, per cent	89.02
Total metallic extraction, per cent	89.91

There was obtained from the metallic contents of the ore:

	Gold, %.	Silver, %.
By cyanidation	87.38	73.49
By concentration	6.85	15.53
Lost in tailing	5.77	10.98

Each stamp worked 94.7% of the total time, with a stamp-duty of 6.12 tons per day. One per cent of the lost time was due to the lack of power, leaving 4.3% for repairs and holidays. This is a satisfactory record, considering that all of the batteries are driven from a single motor drive, and the tube-mills likewise. During the last quarter of the year, each stamp worked 97.4% of the time, with a stamp-duty of 7.26 tons per day; the total extraction for the same period being 91.16%. The direct milling costs for the year were \$3,288 and the indirect 34.1c. per dry ton. During the year the tonnage treated per day was increased from 102 tons for the first quarter to 145 tons for the last quarter. To accomplish this increase, and to treat the higher grade of ore, it was necessary to

add a concentrating addition, and to make many minor changes and additions to the equipment of the mill.

Plant Improvements

The largest item of this expense, \$9965, was that of the concentrating addition, built in May and June, containing 12 No. 3 Deister slimers, with the necessary cones, sumps, pumps, tanks, and the floor space for handling the concentrate. The flow of pulp and concentrate from the tables to their respective sump tanks being in concrete launders below the floor-level, gives a neat and labor-saving installation.

The cost of handling supplies and products to and from the ears on the new spur line is, in cents per ton: Concentrate and zinc, 15; cyanide, 27; lead acetate, 30; pebbles, 50; shoes, 55; and lime, 60.

In April, by additional piping, at a cost of only \$60, the Trent agitators were connected for continuous agitation, described in the *Mining and Scientific Press* of May 3, 1913, by a simple and reliable method, resulting in a longer agitation for the pulp, a saving of power and heat, and less labor for operation. Another beneficial result of this change was that it gave a small continuous feed to the Dorr thickener, and by giving the arms of the thickener a steeper slope, it is possible to decant half of the pregnant solution direct to the silver-tank, and deliver a thick pulp of 1.36 or greater specific gravity to the stock tank. From this thick pulp a 1½-in. cake can be made in less than 40 minutes that is uniform and porous to the washing solutions.

Slag Grinder

A slag grinder and jig were installed to remove the metallic shot from the slag preparatory to sacking it for shipment, and a Case low-pressure fan and oil burner was adapted to the Faber du Faur refining furnace, resulting in but one-third of the oil consumption, faster melting, and less heat and noise in the refinery. These changes aided materially in lowering refining costs. Larger clutches and a stronger chain drive were placed on the tube-mill drive, at a cost of \$1150, allowing the pebble load in the mills to be increased to the maximum capacity of the 100-hp. motor, resulting in a greater output from the mills and an increase of ore treated from 102 tons to 120 tons per day. The speed of the stamps was increased from 98 to 104 drops per minute, with 7-in. drop, by a change of pulleys. This resulted in greater tonnage, with no greater repairs. In 18 months only one stem has been turned. Experiments on one tube-mill proved that if the pebble load could be increased still further beyond the point used in general practice, the resulting greater tonnage would many times repay the greater power and pebble consumption: Consequently, a 150-hp. motor was installed to replace the 100-hp. machine, resulting in a marked daily increase of tonnage.

*Abstract from annual report of the West End Consolidated Mining Company.

averaging 146 tons per day for the last quarter. Two Campbell & Kelly 4-in. centrifugal pumps were purchased and installed at a cost of \$425 to replace Butters pumps, used on Trent agitators, since the two pumps of this make already in service have proved remarkably well suited to the work, with a minimum expenditure for repair work. The Butters pumps were transferred to solution work. With the greater tonnage treated, it became necessary to increase the zinc-box capacity to precipitate the metals in solution, and especially to lower the value of the wash solution used in the filtering operation, in order to reduce the loss in soluble metal from the mill. To carry this saving of solution content to a further point than usual in common practice, where an incomplete replacement of the wash solution in the filter-cake can be made by wash-water, due to dilution of mill solutions, two steel zinc-boxes were installed which were 3 ft. wide, 12 ft. long, and 140-cu. ft. zinc capacity each. One of these is used to give thorough precipitation of the silver solution for wash-solution purposes, and the other to precipitate the long water wash given in the cake, this wash-water staying in a circuit by itself. By this method the filter-cake is washed with wash-solution until the effluent solution from the vacuum-pump is as low in value as the wash solution, then the cake is again washed with wash-water until the effluent solution is nearly as low as the precipitated wash-water. The loss in soluble content before the change was 20c. or greater per ton of ore, which, while excessive, was no greater than the average in the district. This loss was not determined by the inaccurate method of washed and unwashed filter-cake, but by assaying the filtered solution from the sample taken from the discharge launder. This loss is 7c. per ton of ore, or a reduction of 13c., which amounts to a saving of over \$500 per month.

Zinc Lathe

A No. 3 Hampton zinc lathe was installed in the concentrating department, at a total cost of \$233, and the concentrator men cut the zinc necessary. This has resulted in a saving of 2.8c. per pound of zinc shavings, or \$154 per month, besides giving a fresher product and of the right thickness for the boxes. Of this saving, \$135 is credited to the concentrating department for cutting the zinc.

In concentrating pulp after tube-milling it is difficult to obtain a good percentage of the value in the ore in the concentrate, without also including the heaviest particles of quartz, thus making a low-grade concentrate. At the West End, with the heavier tonnage obtained by other changes enumerated above, the tables were overloaded, and to obtain 15% of the value of the ore by concentration the concentrate contained 60% silica. After careful tests, a Wilfley table of half the standard area was installed to reconcentrate the concentrate from the Deisters; also a 1-in. centrifugal pump to raise the concentrate from the 12 tables. These were flattened to deliver the maximum concentrate along with considerable silica. The Wilfley, handling but two tons per day, makes a much cleaner separation, resulting in making but one-half the previous amount of concentrate of but 35% silica, which contains

15% of the value of the ore in 0.5% concentrate. The cost of the installation was \$227, and the saving made in freight and treatment charges amounts to \$170 per month. After this change was made it was not necessary to enlarge the concentrating plant.

Change in Character of Ore

In November the ore in the mill began to change from one entirely quartz and sulphides to one containing a large percentage of oxidized material. The clay content of this ore made settling very difficult, filtering slower, the previous method of discharge impossible, and the method of pumping away the residue expensive for additional water. An installation of 6-in. pipe connecting the filter pump with separate valves to the filter hoppers made it possible by the use of the pump to discharge from the hoppers the entire filter residue in a well mixed pulp. In February, at the slime pumping station, where the slime is lifted 30 ft. over a ridge to join the Montana-Tonopah tailing, a 6 by 20-ft. tank at the end of the flume and pipe was cut out. The pump was also lowered in the excavation to pump from the bottom of the tank instead of from the 24-in. pipe. By this method the slime pulp is not held back in the pipe, but with the swirl in the tank it is kept in constant motion until discharged, resulting in a marked decrease of water necessary for discharge, which is now about 0.9 ton of water per ton of ore.

With this content of oxidized ore, the settling capacity of four 16-in. Dorr thickeners was not great enough, resulting in a slimy overflow, the solids of which accumulated in solution-tanks and pipes. To correct this, a fifth Dorr thickener was installed in one of two tanks previously used for return battery-solution, and a fifth diaphragm pump was added to take the thickened pulp from the new thickener.

Detailed costs were as follows:

	March 1913.	Fiscal year.
Superintendent and foreman	\$0.056	\$0.062
Crushing and conveying	0.080	0.103
Stamp batteries	0.224	0.248
Tube-mills	0.398	0.492
Concentrating	0.113	0.130
Agitating	0.823	1.033
Filtering and discharging	0.171	0.218
Precipitating	0.155	0.260
Elevating and settling.....	0.057	0.103
Motors and lights	0.040	0.036
Refining	0.072	0.097
Drayage	0.008	0.010
Assaying	0.028	0.042
Steam heating	0.136	0.130
Water	0.164	0.214
General expense	0.065	0.110
Total direct	\$2.590	\$3.288
Salaries	\$0.070	\$0.074
Office expense	0.016	0.010
Legal and traveling	0.002
Insurance	0.030	0.036
Taxes	0.034	0.040
Liability insurance	0.018	0.021
Depreciation	0.265	0.158
Total indirect	\$0.433	\$0.341
Total operating	\$3.023	\$3.629

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Hoisting at a Chinese Mine

The Editor:

Sir—The illustrated article under the above head, in last week's issue, reminds me of a feat performed by Chinese coolies in Singapore in 1902. The battleship *Terrible* was lying at the Tanjong Pagar docks, and orders were given to coal her as fast as possible. At 10 a.m. the work started, and by 3 p.m., the same day, 1500 tons of coal had been dumped into the ship's bunkers. This was done by coolies carrying baskets, holding about 200 lb. each, two to each basket, from the storage sheds to the ship. The number employed was never properly known, as the coolies could join in or leave the work as they wished, the job being done by contract. This shows what can be done by crude methods of handling coal. In Borneo, in 1903, I saw a good deal of work done at a placer property by baskets handled by Javanese coolies who were paid about 15c. per day.

San Francisco, July 30.

The Dorr Agitator

The Editor:

Sir—I note with interest Mr. Symmes' interesting description of his agitator, in your issue of July 19. His description of a perfect agitator is certainly that of a practised operator, and one to which we can all subscribe. I regret, however, that I had not informed Mr. Symmes as to the details of the Dorr agitator, to which he refers, and realize that the cut which appeared in our advertisement was not clear enough to give the information which he evidently lacked.

The Dorr agitator has two arms attached by strong hinges to the central air lift, and are arranged so that if for any cause the power is cut off and the machine stopped, the arms can readily be raised to a vertical position. On starting again, they can be gradually lowered until the settled pulp has been brought into suspension and they have regained their original position.

It is entirely true that if the mill crew should allow the arms to remain lowered after the power has gone off for any length of time, with quick-settling sandy material, it might be difficult to start again without breaking something, although in one case we have known of starting after a 24-hour shut-down. My belief is that with the raising and lowering made a matter of entire convenience for the operator, a mill-man who would neglect it would do as much or more damage to all other parts of the mill, and could not be expected to last. This would be comparable to a battery man who might wander away with the feed shut off the battery and the stamps dropping.

During a recent visit to Cobalt, one of the companies there which has just installed a Dorr agi-

tator for agitating concentrate, told me that the machine had been installed in a tank partly filled with tightly packed concentrate left from the use of another agitator. A hole was dug for the central pipe to go in, and the concentrate brought into suspension without any trouble, by gradually lowering the arms.

In comparing our machine with Mr. Symmes', I would think the main difference would be that the latter uses a large number of air lifts, with probably a greater consumption of air, while we use only one, but that both machines should do equally good work. I have faith also in the efficiency of the circulation established in our machine, as adapted to accomplish the best results with the minimum power.

Forestry Service

The Editor:

Sir—In the June 28 edition I note the communication of Mr. J. C. Kennedy of Manhattan, Nevada, one time Deputy Mineral Surveyor for the District of Nevada, but whose commission was revoked by the Commissioner of the General Land Office, July 27, 1909.

The case mentioned by Mr. Kennedy needs only a little fuller explanation of the facts and circumstances to make perfectly clear the consistency of the policy of the Forest Service touching matters of this kind and the action taken in this particular case. For this reason it is deemed proper to give your readers the facts in the case.

The application for patent was made by Mr. Kennedy himself for two claims together, the Pine Nut No. 2 and the Morning Glory lodes, embraced in mineral survey 4073 and mineral application 07533, Carson City series. In accordance with the instructions and procedure applicable to such matters, the notice of application for patent was sent to the supervisor of the forest concerned, who called on the ranger for report, which was promptly made. The report showed that on the Pine Nut No. 2 there was a valid discovery of mineral and that improvements and development work to the extent of \$15,000 was manifest, and suggested that the claim be recommended for patent. As to the Morning Glory, the report showed that the development work was in surface ground and country rock. The dimensions of the workings were given and an estimate of their value of \$225, or less than half the amount required by law. It was pointed out that the applicant, Mr. Kennedy himself, sought to apportion to this claim, as contributing to its development, a portion of a tunnel on the Pine Nut claim, which tunnel did not even run toward the Morning Glory claim. Mention was made of the only drift from this tunnel, which pointed in the general direction of the Morning Glory claim, but it was stated that even this drift, if continued, would come out of the hillside across the gulch from the claim proper. No technical knowledge was needed to recognize that such work was not properly credited to the Morning Glory claim. Discussing the matter of mineral showing, the ranger stated in the report that the discovery shaft was in country rock with no sign of

mineralized rock to be found in the vicinity. None of the trenches showed any signs of mineralized rock beyond a slight iron stain, and such material has not been known to carry metal in that district, in which the ranger had spent more than five years, and assisted the official mineral examiner in the examination of many mining claims. The claim was examined twice. Once in company with Mr. Kennedy himself, and later with two other practical local people, who were named as corroborating the statements of the ranger. From this it will be seen that insufficient mineral showing, while mentioned, was secondary to the other requirement of \$500 development work. It also shows that the ranger's findings were supported by other witnesses; that good faith was not only lacking, but that bad faith was manifest. Seeking mineral patent to land of this kind and in this way, and advertising it to the public, to investors, or even to stockholders, is not prospecting, but 'wild-catting,' a practice to which the Government cannot give its sanction, and a distinction which the Government, through its field service, is trying to make clear to the public, and through ignorance of which investors have been bilked and working people robbed of a life-time's savings.

The ranger's report, forwarded to the district office with the supervisor's endorsement and approval, was considered by the mineral expert, who, along with the administrative officers, concluded that the expensive expert examination to determine sufficiency of mineral showing was unnecessary, since the other charge showed bad faith, was grounds for refusal of patent, and was provable by other testimony. Mr. Kennedy's article would give the impression that claims upon which \$10,000 had been expended in development had been held up on the unsupported opinion of an inexperienced ranger as to the insufficiency of mineral showing, when the facts are that good faith could not be presumed, as Mr. Kennedy seemed to think it should be. The matter of insufficiency of discovery was not the unsupported opinion of the ranger. The ranger was not inexperienced in such matters, the claim upon which the \$10,000 development work had been done was reported upon favorably, and not a thing stood in the way of its speedy passage to patent except that for which Mr. Kennedy is alone responsible, namely, his attempt to make it carry to patent a claim not meeting the law's requirement as to development expenditure, to say nothing of its questionable character from the standpoint of mineral showing.

In the closing paragraphs of his article Mr. Kennedy makes it plain that he chafes under the present policy of the Government, the basis of which he declares to be in "obscure and inexplicit clauses" in the law. But since under guise of mining patents large cattle companies have acquired watering places that control vast areas of range, timber speculators seized large areas of the most valuable timber lands, power companies sought, and to quite an extent secured, monopoly of power development, when town-site boomers have fleeced residents and settlers at our foremost mining camps for lots upon which to live and do business, and exploiting concerns, by the

same means, secured control of water frontage and forced tribute from individuals who of necessity had to meet their demands, is it not time that laws ceased to be obscure and inexplicit? Charged with heavy responsibility in the execution of certain laws, the Forest Service is seeking diligently to discharge its duty to the public, and in doing so has sought earnestly to ascertain the intent of every part of every law with which its work is concerned. Uncertainty, obscurity, and darkness serve only to promote ignorance and wrong, while light and the open road make for justice and progress.

E. A. SHERMAN.

Ogden, Utah, July 24.

Inclined Baffles

The Editor:

Sir—Referring briefly to Mr. Spicer's letter, in the issue of June 21, concerning the use of the inclined baffle to increase the settling capacity in slime-settling tank, contrary to his sweeping statement that there is no advantage in the system, I have found the inclined baffle of marked benefit in the settling-tank, but like many other good things that are condemned off-hand, it is necessary to understand the principles involved.

The inclined and vertical glass cylinders show clearly that there is a decided advantage in the rapidity of settlement in the inclined cylinder. Mr. Spicer, while acknowledging that the cylinders indicate the possibilities, has apparently not tried to solve the principle involved, and cites hearsay evidence and ignorant application to condemn it.

The reason for this is apparent when his connection with a certain patented device in which the application would be expensive is taken into account. A statement like his, is certainly not credible to the intelligence of engineers who have solved problems in which it was not possible to get even an optical illustration of the solution.

JOHN E. ROTHWELL.

Butte, Montana, June 30.

Use of Steel Points for Core-Drilling

M. L. Martel, in an article that is appearing in the *Bulletin de l'Industrie Minerale*, furnishes an interesting account of the use of steel-pointed drills. The recent application of granules of steel instead of diamonds has shown that in many instances they offer advantages over old methods of boring. The principal advantage of steel granules is in the matter of cost, facility in obtaining bores of large diameter, and boring very hard rocks—such as corundum. It is hard broken rock that this method of drilling displays its superiority over the diamond-drill. The difficulty with steel-pointed drills appears when the bore-holes are far removed from verticality. Under favorable conditions the granules have penetrated 52 ft. in 24 hours, but generally, in ordinary ground and moderate depth, the daily advance is from 16 to 20 ft. This mode of boring seems destined to be extensively employed.

France has spent \$35,000,000 in planting trees on the watersheds of important streams.

Special Correspondence

NEW YORK

THE COPPER MARKET.—FEDERAL MINING & SMELTING CO.
RESULTS OF CONCENTRATING WITH THE McQUISTEN TUBE.
—EFFECTS OF AFFAIRS IN MEXICO.—COBALT, PORCUPINE,
AND TONOPAH MINES.

The walk-out of the Lake Superior copper miners, following hard on the heels of the resumption of copper buying, was quickly turned to account by the metal sellers, and sales were made at 15c. per pound on July 25 in New York, while the cables reported that Amalgamated was asking £69 5s. (15 $\frac{1}{4}$ c.) in London; Phelps, Dodge & Co., the American Smelting & Refining Co., and Aron Hirsch & Sohn being out of the London market for September delivery. In New York the last sale of Lake copper was made at 14 $\frac{3}{4}$ c. on July 24, and Calumet & Hecla, Quincy, Mohawk, Wolverine, Copper Range, and all the other Lake companies announced that they are out of the market until the strike is settled. Exports of copper for the week ended July 24 were 3981, and the total exports since July 1 have been 19,375, or over 4000 tons less than the same period of last year. It is computed that total deliveries this month will amount to 121,000,000 lb., corresponding to a further decrease of 15,000,000 lb. in the surplus. At this rate of progress the copper market will soon be running on a deficit, statistically at least. Reports from Tanganyika bring a gleam of hope. According to the statement of the managing directors, it is proposed to build four more smelters at the Kansanski mine, which within a few months will bring the production of copper up to 6,000,000 lb. per month. However, we have heard reports from Tanganyika before, and smelters which can be built and operating in the heart of Africa in a few months sound no more plausible than many earlier statements. As a matter of fact, if the Lake mines stay shut down for a time and Mexico continues in chaos, it looks decidedly as though the copper market is in for a squeeze that may send that metal back to where it was last year.

Spelter seems to have turned the corner and has advanced to 5.3c. per pound, and producers are hoping that it will continue to advance. The Federal Mining & Smelting Co. has bloomed out as quite a producer of zinc, thanks to the McQuisten tube concentrator, and gives every evidence that it will continue to expand. The ores in the Federal properties became so refractory with the advent of zinc in depth that its operating profits almost disappeared, but were resuscitated by the tube concentrator, which yielded zinc concentrate at a good operating profit. This has been so satisfactory that the Federal company has been acquiring a number of deep mines and reopening them, and the Helena-Frisco, which was purchased last November, has just been unwatered. Through the Helena workings it is hoped to reach the orebodies in the Flynn and Star mines, two other recent purchases. Federal is now earning its dividends and shows excellent signs of 'coming back' in good shape.

Among the incidental effects of Mexican conditions are many happenings like that in New York last week, when Jose M. Ortiz was denied an injunction to restrain Voiney D. Williamson from selling 15,855 shares of stock in the International Metals Co. which had been deposited as security for a loan of \$60,000. Ortiz contended that under present conditions the shares would bring next to nothing and wished to have the sale postponed, but the presiding judge took the position that under present conditions it would be necessary to postpone the sale indefinitely and denied the injunction. The incident is typical of the less obvious losses which investors in Mexico are suffering as a result of present conditions there.

Silver mines are making a good showing. The La Rose, in its financial statement on July 1, shows cash and ore on hand ready for shipment amounting to \$1,831,298. The Nipissing does almost as well with a total of \$1,463,401 in cash and ore and bullion on hand or in transit.

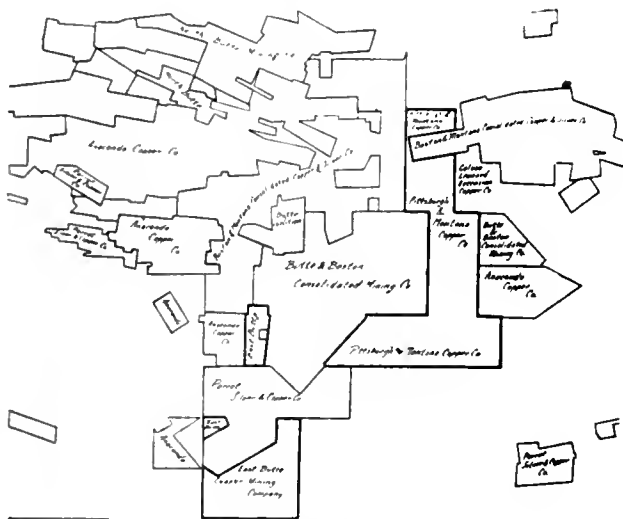

The Tonopah Mining Co. recently paid a dividend of 40c. per share, but accompanied it with a note that the next dividend will probably be at a lower rate. The Company has paid a total of \$10,850,000 in dividends to date. Tonopah Merger is reported to be making a good showing. Cobalt is reviving in interest. Nearly all the shareholders in Crown Reserve have subscribed for the shares of the Porcupine Crown Co. and the entire block of 442,203 shares was taken at 80c. per share. The regular dividend on Crown Reserve will be paid August 5. This Company owns 1,400,000 shares of Porcupine Crown, and it is hoped to have the latter yielding dividends before the end of the year. The Nipissing has both its mills in operation and has practically discontinued ore shipments.

BUTTE, MONTANA

BUTTE & ELY COPPER CO. AND THE MERGER AT ELY, NEVADA.

—BUTTE & SUPERIOR MILL IN FULL OPERATION.—VEIN
FOUND BELOW FAULT IN ALEX. SCOTT CLAIM.—RICH ORE
IN THE RUBY MINE.

Some local stockholders of the Butte & Ely Copper Co. are far from satisfied with the proposed merger of that property into the Consolidated Coppermines Co. at Ely, Nevada. They say that, of all the various companies which are considered in the merger, the Butte & Ely is the only one with any considerable amount of cash on hand. These dissatisfied stockholders claim that the other companies have their eyes on the \$250,000 on hand and are trying to get it without a fair return to Butte & Ely interests. A receiver for this Company has been asked for, and a

PLAN OF PROPERTIES AT BUTTE.

court order to restrain the majority interests from committing the property to the merger on these terms. Duluth interests control Butte & Ely at present.

The concentrator of the Butte & Superior Copper Co. has at last been remodeled in both sections and is now running at full capacity of 1200 tons per day. More than 8000 tons of 50% zinc concentrate will be produced in July, according to estimates, and this is expected to be increased to 10,000 tons in August. The confusion of experimenting seems to be nearly at an end, and the plant is beginning to take on a business-like look, which is encouraging. No first-hand information is available as to what success is being had with flotation, but the fact that that part of the plant is actively at work is suggestive that the results are satisfactory. An extraction of 90% has been claimed, but that seems almost too good to be true.

Some years ago the Boston & Montana Copper Mining Co. did some diamond-drilling and otherwise prospected the Alex. Scott claim on the 1200-ft. level. The results were so disappointing that the opportunity to purchase the ground was let slip; but now the same interests are compelled to pay a big toll to the owners of the Alex. Scott for the following unforeseen reason. Below the 1200-ft.

level, a vein was subsequently found beneath a fault, apexing in the Alex. Scott ground and dipping into the Boston & Montana ground lower down. This vein contains profitable ore and has been worked extensively by the Alex. Scott company. The vein in its steep southerly dip intersects the Colusa shaft of the Boston & Montana ground about the 2000-ft. level, so that in order to protect this shaft properly from the mining operations on the Alex. Scott, it is now necessary for the owners of the Boston & Montana ground to purchase a good-sized block of the vein at a liberal price. It is said that another stipulation of the deal requires that the purchaser agrees to refrain forever from bringing up any apex litigation over rights to this Alex. Scott vein. From all of which the moral might be drawn that in Butte a mining claim sometimes has veins thrust upon it, even when surface indications suggest the contrary.

Butte so far eclipsed in importance the other mining operations of the state that a first-class find can be made in a nearby camp without causing even a ripple of excitement in Butte's mining circles. As an illustration, some lessees in the Ruby mine, a gold-silver producer, 17 miles north of Butte, opened a fine body of high-grade shipping ore recently, which would have caused a furor in most Nevada towns. This find was given current notice in the newspapers, but affected the amount of activity at Butte in no way. No one not directly interested came up to see the ore, and the newspapers are paying no more attention to the matter, although the ore-shoot is expected to yield from \$100,000 to \$200,000 in the short time necessary to extract it. The mine is in dacite similar to that at Goldfield.

BOSTON

LOCAL INTEREST IN THE UTAH METALS MINING CO.—GREENE CANANEA STOCK PROPOSALS.—NORTH BUTTE INTERESTS BEING EXPANDED.—ORGANIZATION OF DOUGLAS COPPER CO.

Boston people are much interested in the recent statement issued by the management of the Utah Metals Mining Co., that the tunnel being driven through the mountain from Tooele to Bingham, Utah, had been completed. Utah Metals, which is a combination of the Bingham Central Mining Co., the Bingham Standard Copper Co., and the Bingham Metal Mining Co., has been pushing the completion of this tunnel for over three years. Previous to that time the three individual companies concerned in the amalgamation had been putting in more or less effort toward the completion of this same tunnel. It measures 11,494 ft. in length, is single tracked at present, with 35-lb. rails, and electrically lighted for its entire length. Fifteen different mineralized veins have been opened, and a large amount of water made available for commercial use. The Boston men interested in the undertaking are James E. Rothwell, William M. Wadden, M. Allison Taylor, W. E. L. Dillaway, Cabot J. Morse, and Harry L. Ayer, while from Salt Lake City are E. P. Jennings and William E. Hubbard. The above gentlemen and Arthur B. Martin, of Chelsea, Massachusetts, comprise the directorate.

Local investors are anticipating a new trading sensation in the coming certificates for full shares and certificates for fractional shares of Greene Cananea stock. The Company has recently changed the par value of shares from \$20 to \$100, exchanging one share of the new stock for five of the old. To those who have not even parts of five shares, the Company is giving fractional shares. It is the latter phase of the situation that Boston looks for untoward developments. As now planned, the holder of a fraction cannot vote his stock, nor can he receive dividends upon these fractions. Boston people think that someone has erred in this latter decision, as it fails to see how any company can refuse the ratio payments of dividends to the holders of fractional certificates. A fractional certificate represents a pro rata share of Greene Cananea's assets, as does a full share. Greene Cananea is now outputting about 100 tons of bullion per day, including the production from the Miami property, since the latter part of May.

Announcement is made here of the holding, under an

option agreement, of the Victoria property in the Bingham district, Utah, by the Bingham Copper Co. The Victoria claims adjoin the Eagle & Blue Bell property, also controlled by the Bingham Mines Co., which itself is a reorganization of the old Bingham Consolidated Mining & Smelting Company.

With regard to the policy of expansion by the Tuolumne and Bingham companies, Boston also is following closely the news of the constant acquiring of territory by the Cole-Ryan interests in the Butte district, primarily for the interest of the North Butte Co., some \$1,000,000 already having been expended for over 1000 acres of territory. It is felt here that such an undertaking is too much for the rejuvenated North Butte and that a new company will be formed to operate the new claims. The North Butte will be given a large stock interest in the new company, practically a working control, and will later probably absorb it, if the developments turn out as expected. The argument advanced at Boston is that North Butte can afford an investment of, say, \$1,000,000 in such a plan, but is not able to altogether finance the purchase, development, and management of 1000 acres of prospect territory.

The formation of the Douglas Copper Co., owning 440 acres of land in the Lake Superior district, has not been particularly well received here. It is to be a St. Mary's Mineral Land management property, with the usual \$2,500,000 capital, 100,000 shares, par value \$25. Of the capitalization, 50,000 shares will be given in payment for lands, of which 160 acres came from the St. Mary's Mineral Land Co., 160 acres from the Sheldon-Douglas interests, and 120 acres from the Boston & Lake Superior Mineral Land Co. The territory of the new company underlies the No. 1 and No. 2 shafts of the Ahmeek property, two rich districts. The company's offices will be in the Sears building, Boston.

JOPLIN, MISSOURI

RECLAIMING SLUDGE ORES FROM GRANBY LAND AT ORONOGO.—NEW CONCENTRATING PLANTS CONSTRUCTED.—ZINC AND LEAD NOTES.

A sludge mill, equipped with four tables, is being erected by Charles Simpson and Charles Morris on a lease on the Pinnacle Mining Co.'s tract on the Granby Mining & Smelting Co.'s land at Oronogo. For about three years the sediment from the Pinnacle mine, which is comparatively a new producer, has been collecting in the bottom of several old sludge ponds, and this sediment carries enough zinc sulphide content to make its remilling profitable. When the old sludge is all cleaned up, it will be taken direct to the mill. The treatment of slime is growing to be more common throughout the district.

At the Oronogo Circle mine, adjoining the Pinnacle lease, the slime treatment is considered of much importance, and at this property is found one of the largest and most complete sludge mills in the district. As a rule, the sludge carries from 3 to 5% zinc sulphide and a small percentage of galena, where there has been any appreciable amount of this ore in the original dirt from the mine. The product from the sludge tables does not command the high figure paid for the jig concentrate, yet in some instances the treatment of the slime affords the additional profit that may permit of a mine being operated successfully.

At various points throughout the district new concentrating plants are being erected. In some instances the building of these mills does not represent additional milling capacity to the district, as old mills that have suspended operation are used in the construction; however, several entirely new plants are going up. At Miami, Oklahoma, the Lost Trail Mining Co. has completed a plant of 300-ton daily capacity on a lease of the Frosty Morning Mining Co.. In the same district the Gray Top Mining Co. has completed a new plant of 300-ton capacity and is now making 'turn-ins.' At Duenweg, Missouri, the Wilson Mines Co. is increasing the capacity of its mill from 300 to 600 tons, and the remodeled plant will be ready to run by the latter part of August. The old mill averaged 120,000 lb. of zinc sulphide concentrate weekly for the past year or more. New jigs, crushers, and rolls are to

be installed, and the shell of the mill almost doubled in dimensions. The operators expect to hoist as high as 1600 'cans' per day. A 40-ft. face of ore in disseminated ground is being worked at a depth of 172 ft. The extensive underground work, resulting in the opening of long drifts, has enabled the Company to hoist a much heavier tonnage than formerly; hence the decision to increase the milling capacity. Pumps throwing 300 gal. of water per minute hold the water to the working level with ease. Several sub-lessees are at work on the Wilson ground, one of these, the old Newsboy, having just completed the construction of a 150-ton mill, the plant having been moved from an adjoining lease. This makes the fourth mill to be erected on the old Newsboy workings, the gradual increase in ore prices since the first activities on this ground having made it possible for the various operating companies to handle thinner and thinner ore, and yet make a profit. On another sub-lease of the Wilson tract, Brown & Co. have a prospect on which they intend soon to begin the construction of a small concentrating plant. On the Center Creek Mining Co.'s land at Webb City, the J. M. Short Co. is constructing a mill to be known as the Comanche. The plant, which is made up chiefly of machinery taken from the old Yellow Dog mill, on the Underwriters Land Co.'s property, is to have a capacity of 200 tons per shift. The mill is on the site of the Good Shepherd, which was burned to the ground a number of months ago. Operations

CONCENTRATE AT A JOPLIN MILL.

are conducted in soft ground at a depth of 160 ft. Improvements at one of the mills of the American Zinc, Lead & Smelting Co., at Prosperity, have been completed, and the mill, the only one of four now operated at Prosperity by this Company, is running steadily, the weekly output being about 225,000 lb. of zinc sulphide concentrate and 30,000 to 50,000 lb. of lead. At the Redbush mine, on a lease of the Stewart land, at Neck City, where recent drilling has shown good ore, a plant is soon to be erected. At Spring City, the 150-ton mill of the Lulu V Mining Co. is completed and will be ready to run within a week or two. The Company used the mill of the Spring City Lead & Zinc Co., where operations have been suspended. The Lulu V mine is in virgin territory.

At Stotts City, in the eastern part of the district, six drills are at work. One of these is being operated by the Grasselli Chemical Co., one of the largest zinc-buying companies in the district. Only recently the Company began prospecting in this district, its work in the past having been confined solely to the purchase of zinc ores. The Company has prospected on the Riseling estate in the western part of Joplin recently, following which it moved its drill to property which it owned in fee in the Stotts City district. Virtually all the drilling in that district will be done on virgin ground. On an old lease, a sludge company is completing the construction of a small plant which will handle the lost slime from previous milling operations.

At the beginning of August 1913 zinc ore prices range

from \$41 to \$44, assay basis of 60% metallic zinc, while lots carrying a higher percentage of metallic zinc bring a premium and in a few instances bring as high as \$47 per ton. The lower grades range down to as low as \$30, settlement. At this time last year the record prices of the district were prevailing, the basis for blende being \$62 to \$64, with choice ores bringing \$67. Spelter which is now firm at \$5.25 was then strong at \$7.25. East St. Louis quotations are used. The production is about 4500 tons per week, compared with 6000 tons a year ago. Calamine sells for \$22 to \$23, assay basis of 40% metallic zinc, with top grades commanding as high as \$26. A year ago the basis range was \$30 to \$33, with top grades selling up to \$38. Lead ore is unchanged at \$52.50 per ton, with metal quoted at \$4.25. A year ago metal brought \$4.60 and ore sold for \$60.

PORCUPINE, ONTARIO

STAMP-MILLS IN OPERATION AND BEING ENLARGED AT PORCUPINE.—MINE DEVELOPMENTS.—WORK AT COBALT.—INTERNATIONAL GEOLOGICAL CONGRESS ASSEMBLES.

The Porcupine gold district proper, exclusive of the Swastika and Kirkland Lake districts, has now 11 stamp-mills completed and in course of construction, having an aggregate capacity of 1665 tons of ore per day. The stamps now in operation number approximately 175. Plans now under way for the increase of equipment are as follows: The Dome will add 60 stamps, bringing the total number up to 100; the Hollinger will increase its mill from 40 to 80; the Jupiter, from 12 to 25; the Dome Lake, from 10 to 40; Porcupine Crown, formerly the McEnaney, from 10 to 40; Three Nations, from 10 to 25; the Rea, from 5 to 20; and the Hughes, from 3 to 20 stamps.

The entire force at the Hollinger has been put on an 8-hour day basis without change in the wage scale, anticipating the operation of the recent amendment to the Mining Act fixing the working day for miners at eight hours, which comes into force January 1.

At the Dome Lake a new orebody has been discovered by a cross-cut from the main shaft at the 180-ft. level, and shows free gold. The shaft of the Hughes has been sunk to the 300-ft. level, where a promising quartz vein, upward of 10 ft. wide and showing free gold, has been found. Deep development has shown that the veins are continuous and maintain their metal content. The directors have decided to adopt the cyanide treatment in connection with the new mill. While the forest fires raged in the district early in the month, the powder mill of the Pearl Lake exploded, causing considerable damage to the plant, but without injury to anyone. The mining claims owned by the Crown Chartered, in Porcupine, were put up for sale at auction on July 9, but were withdrawn, the bidding being under the reserve price. Important new discoveries are reported in the Kirkland Lake district. At the Burnside property, adjoining the Foster, which is being developed by a Halleybury syndicate, a surface vein showing free gold has been stripped for 50 ft., and a 19-in. orebody exposed, the gold content of which is stated to run \$700 per ton. The Teck-Hughes has a shaft down 120 ft. on No. 1 vein, and is cutting a station at the 100-ft. level. Sinking has been started on No. 2 vein which shows free gold at the surface. The Wettlaufer has sunk on the Ovi vein to a depth of 50 ft., where there is 4 ft. of rich ore. The Bigelow property, in northeast Teck township, has a 12-ft. vein showing good gold content. The first clean-up of the 5-stamp mill at the Foster, after a month's run, during which about 10 tons of ore per day was treated, yielded 350 oz. of gold. The shaft is down to 170 ft., the ore holding well at that depth.

A winze was put down 20 ft. below the 650-ft. level of the Temiskaming mine. The Sebeca Superior has gone on a regular dividend basis of 10% every two months. The Company has cash in hand to the amount of \$127,249, and ore in transit to the approximate value of \$65,000. The Silver Cliff shipped a car of 18 tons of ore last month which realized \$15,000, and will probably send out another carload. Five veins have been cut in the workings from the

Lake shaft. The Cochrane is driving on the 200-ft. level on a vein 6 to 10 in. wide, showing native silver. The vein was barren at the 100-ft. level. The Sterling mine, near Arsenic lake, in the Elk Lake district, which has been the subject of considerable litigation, was sold by order of the court, on July 8, to M. B. Sullivan, of Boston.

A number of noted geologists from abroad have arrived at Montreal in connection with the International Geological Congress, the principal session of which will be held at Toronto, August 7 to 14. A number of excursions to regions of geological interest will be held before that date, the first of which left Montreal for various points in Quebec and the Maritime Provinces on July 13.

JOHANNESBURG, TRANSVAAL

DEVELOPMENT OF THE MODDERFONTEIN GOVERNMENT AREAS.—TROUBLES AT THE CINDERELLA DEEP MINE.—RAND MINES, LTD., MEETING.

Among the plethora of company meetings held during the last week in May, and practically representing the strength of the entire length of the Rand extending from Springs to Randfontein, those dealing with the progress of that part known as the Far East Rand have attracted most attention. There is, for instance, the property known as the Modderfontein Government Areas, where during the week a 'reef' find of the highest importance has been made in the southeast shaft, following those in the northern shafts where the Main Reef was intersected a short time ago. The property is an extensive one, consisting of 2633 claims, or say 4000 English acres, surrounded on every side, save the southeast, by well proved properties, among them the Brakpan, Modder Deep, Modderfontein, Modder B, and Geduld. Being so surrounded, four shafts were started without recourse to preliminary boring operations, an unusual thing on the Rand, but the results have proved that this policy was the correct one. Speaking generally, it was considered that the northern section of the property was most valuable where the 'reef' was nearest to the outcrop, with the result that the sinking of the northern shafts was watched with considerable interest. Four shafts were started, two on the northern and best known area, and two on the southern area regarded as of more doubtful value. In the two northern shafts the reef was cut at depths of 2273 and 2395 ft., respectively, from the surface, and although the gold content at the point of intersection by the shafts was profitable, it did not come up to expectation, and, being in what was considered the most promising part of the property, the outlook was not encouraging. However, on being driven on, the ore improved, and at the beginning of June had quite come up to former anticipations. On May 21, however, the southeastern shaft, situated in what was regarded as the most doubtful section of the property, cut a fine body of 'reef' at a depth of 3580 ft. from the surface, averaging \$16 over a width of 55 in., thus improving on the actual results obtained on driving in the northern section of the property. It will be seen that three-fourths of this extensive property has practically come up to anticipation, and little fear is expressed that the southwest shaft, with the Brakpan mines as a neighbor, will also follow suit and intersect a profitable 'reef.' It is not only the Modder Government Areas which have benefited from these satisfactory developments, but the prospect of other Government Areas lying to the south, for which tenders have been invited. With such excellent results on the southern section of the Modder Areas, coupled with those obtained at Springs, the mining prospects of the Schapenrust-Brakpan Government Area, for which tenders have been invited, are considerably enhanced and the uncertainty regarding its value materially reduced. These four East Rand improvements have been the outstanding feature of the work, for it is on the Far East Rand that the future increased gold production of the Rand goldfields so largely depends.

It has been decided to temporarily stop milling operations at the Cinderella Deep mine at Boksburg, and although this step has been somewhat expected for some time, the decision has cast a cloud over the town and district, following as it does the closing down of the East Rand Extension, Boksburg gold mine, Apex, and Benoni, while the disastrous strike at the New Kleinfontein has added somewhat to the prevailing depression. The Cinderella Deep belongs to the well known Albu group, whose managing director, Sir George Albu, has very properly earned a reputation for thoroughly testing several difficult mining properties, and it was hoped that despite the serious losses sustained during the last few months, it would not necessitate closing down the mill. In May, the 70 stamps and three tube-mills crushed 16,120 tons, but the value of the yield, although \$5.68 per ton, resulted in a loss of \$19,300. According to reports, there does not seem to be any prospect of the working cost of \$6.94 being brought down to a reasonable figure. The trouble is essentially in mining, the Cinderella Deep being one of the deepest mines on the Rand, but stopping operations have for some time been principally confined to the 'rise' portion of the mine. Unfortunately, the Cinderella Deep is at present a single-shaft property, and, like the City Deep, experiences the greatest difficulty in efficiently ventilating the workings. I have previously pointed out that the temperature in some parts of the mine exceeds 90°F., a temperature not conducive to successful work and one which

MAP OF RAND DISTRICT.

apparently cannot be reduced until the new shaft is connected with the present workings, which no doubt will take another year to accomplish. The closing down of the Cinderella Deep mill, on account of the mining difficulties, does not enhance the reputation of the engineering and mining talent of the Rand, because, if the ventilation difficulty was properly tackled, success would be assured. There is little difficulty in ventilating a deep mine on the Rand in a proper manner. If only the task is gone about in a workmanlike method; but if attempts be made to ventilate a mine in a faulty manner, no task becomes so difficult. Then the Cinderella Deep has earned a bad reputation for air-blasts, caused to a large extent by faulty methods of mining in ground conducive to the occurrence of these peculiar phenomena. What with one drawback and another, mining under present conditions and methods at this property is not by any means an easy task. It is clear that a monthly tonnage of 16,000 tons is far too small wherewith to earn a dividend for the shareholders, and doubtless when worked on an adequate scale the mine will give a good account of itself.

During the week ended June 23, the annual meeting of the Rand Mines, Ltd., a concern either controlling or holding interests in nearly every mine of marked value on the Rand, was held. These interests extend over three-quarters the whole length of the Rand and practically embrace all of the deep-level mines and properties worth having. The history of mining operations carried on here may be regarded as the history of the Rand.

General Mining News

ALASKA

CORDOVA

Mining at Knik and in the Willow Creek district is being rushed this season, in spite of the handicaps that the operators are under. The Alaska Free Gold, Alaska Gold Quartz, and Gold Bullion mines are all milling steadily. Generally, the district is opening in a promising manner.

FAIRBANKS

Twenty tons of ore from the Reliance Mining Co.'s claim yielded \$134 per ton crushed. The Company has acquired the Wild Rose claim, between the Soo and La Rose claims on Dome creek.

JUNEAU

The June operations of the mines on Douglas island resulted as follows:

	Alaska Mexican.	Alaska Treadwell.	Alaska United.
Development, feet	80	400	775
Ore crushed, tons	18,207	74,900	36,197
Gold by amalgamation	\$28,064	\$110,014	\$47,189
Concentrate, tons	424	1,426	865
Gold by cyanidation	\$51,772	\$100,498	\$42,232
Total realization	51,254	208,407	89,517
Operating costs	23,113	83,391	50,875
Construction	2,791	15,640	4,114
Profit	25,350	109,375	34,528

KETCHIKAN

According to the Ketchikan Miner, the Great Boulder Proprietary Co., of Kalgoorlie, Western Australia, has taken over the options of the Alaska Venture Syndicate, which include the Bugge and nearby properties.

NOME

The Nome-Montana dredge started working in the Solomon district on June 14. The American Gold Dredging

HERMING'S HYDRAULIC MINE, NEAR KNIK, ALASKA.

Co. has launched its dredge, which should be at work soon at the mouth of Peluk creek.

SUSHANNA

Gold worth \$3600, the first shipment from the new district north of Kennecott, has been received at Dawson, Yukon Territory, and is now on view. The gold was recovered from a claim on Little Eldorado creek in two days by two men shoveling. T. Doyle obtained \$27 per pan on his claim. A. Taylor and T. Doyle, who are at Dawson, stated that all the claims in the district are staked, and prospectors should not go to the new field without several months' supplies.

VALDEZ

The Midas copper mine, near this place, is being reopened after a short shut-down due to disagreement between the owners and the Alaska Syndicate, which has an option on the property. Over 1800 ft. of development has been done, and reserves are given as 200,000 tons of 7% copper ore, with also some ore containing gold and silver.

ARIZONA

GILA COUNTY

(Special Correspondence.)—Because of the large amount of water and comparatively small amount of power available, work at the Magma has been held back to a great extent during the past few months; but such work as has been performed has been extremely satisfactory, and there is today an excellent showing of ore in both the 650 and 800-ft. levels east. When the transmission line from Roosevelt via Miami has been completed, the Magma will have ample power, development work will proceed more rapidly, and within the next few months construction of a concentrator will begin. It is said that the Company will begin purchasing mill equipment within 60 days. Considerable plant has already been ordered to be delivered at the mine, to be installed in time to begin operation when the transmission line is complete. Three 250-kva. transformers for the sub-station, to reduce the voltage from 45,000 to 2200 volts; three 75-kva. transformers, to reduce the voltage from 2200 to 440 for the mine pumps; three vertical Aldrich pumps, to be driven by 75-hp. motors; a 225-hp. motor to drive the compressors, and other machinery have been ordered. The Magma is shipping the usual amount of high-grade copper ore to Florence by team, thence by rail to the El Paso smelter. The underground force remains at about 40 men and will not be materially increased until the advent of the electric power. About 500 ft. of diamond-drilling remains to be done by contract. Ore has been found in all of the holes drilled.

At the Calumet & Arizona, south of Superior, the shaft is more than 500 ft. deep, and considerable iron and copper carbonate was reported as cut near that depth. A pump station is being cut at the 500-ft. level. The shaft is making about 6000 gal. of water per day. The main working adit is about 1000 ft. long, and stringers of carbonate and sulphide ore have been passed through. The Calumet & Arizona company's superintendent of motor power, Mr. McKee, visited the mine recently and took measurements for a 15-drill compressor, which may be installed at the plant in the near future. Thomas Ryan, diamond-drill contractor, who has been drilling the Magma property for several months, may contract with the C. & A. to drill 1500 ft. on the property.

Miami, July 26.

The report of the Arizona Commercial Copper Co. for the year ended June 30, 1913, states that the surplus amounts to \$284,523. The Copper Hill shaft has been enlarged and retimbered 390 ft. from a depth of 418 ft. below the collar to the bottom of the old shaft, 808 ft. below; and it has been sunk 317 ft. farther to a depth of 1125 ft., and 450 ft. of drift has been repaired on the No. 3 level. Driving covered 158 ft. on the No. 4 level, and connection has been made with the Gray mine of the Old Dominion company. On No. 7 level, two narrow sulphide veins are being opened by a drift and raise, respectively; and No. 8 level is in limestone. There has been no leasing since the beginning of 1913, and no ore has been shipped since then.

Reports given out as being official are that what is known as the Christmas mine, 10 miles north of Winkelman, has been bonded for \$1,000,000 to Eastern capitalists. B. P. Cheney, who is well known in financial circles, with headquarters in Boston, is the principal in the undertaking. It is stated that work will begin on this mine in about fifteen days.

CALIFORNIA

The June production of oil from all counties totaled 8,109,941 bbl. gross, compared with 8,098,138 bbl. in May. The consumption on the fields is included in this quantity, but owing to the general adoption of electric power this item is decreasing steadily. Operations during June were as follows: rigs completed, 48; drilling, 373 wells; producing wells, 5997; completed, 64 wells; and abandoned, 17 wells.

AMADOR COUNTY

A good quality of ore has been opened in the Oneida mine, adjoining the South Eureka, and 10 stamps of the

old mill are working. The Central Eureka has resumed shaft-sinking.

ELDORADO COUNTY

The new mill at the Homestead mine began crushing ore this week. J. B. Farnsworth is in charge of the work. The mine is being worked by Sacramento parties.

MODOC COUNTY

An ore-shoot, over 100 ft. long, has been opened in the Lucky Dutchman lease of the Sunshine property, and 100 tons of \$60 ore has been mined. This will be shipped to Salt Lake City. A winze is being sunk in ore below the main adit-level of the Sunshine by a lessee, J. Miller. The lease on block No. 8 of the Sunshine, north of the adit, has opened good ore. The Modoc Mines Co. has a shaft down 200 ft. and is equipped with a steam hoist, the only one at High Grade. Water has been troublesome, but driving on the 50, 100, and 200-ft. levels on the vein is being started. W. Wrigley, Jr., and others, of Chicago, are interested in this property. The Gold Nugget and Gold

SUNSHINE PROPERTY, HIGH GRADE.

Shore claims are being prospected. A postoffice and telephone has been installed at High Grade, and the district is said to be quite promising.

NEVADA COUNTY

A company known as the You Bet Mining Co. has been organized, by Los Angeles people, with a capital of \$200,000, to develop the claims of the late Jerry Goodwin at You Bet.

PLACER COUNTY

Construction work has commenced on the Yukon Gold Co.'s dredge near Auburn. The machine formerly worked at Oroville. The claims of Charles Gaws, on the North Fork of the American river, one mile below Auburn, have been bonded to a syndicate that will test their value for dredging. Borings will be taken immediately. Iowa Hill, an old mining town, is again booming. At the Bumps Cañon claim a placer machine of 500-cu. yd. capacity is at work.

PLUMAS COUNTY

According to the *Greenville News*, mining in the Seneca district is increasing in activity. Sol Camp and Grant Snyder, representing Salt Lake interests, have been examining practically all of the properties cutting the old channel under the lava cap. A deal is now pending for the purchase by their people of the Cameron old channel property. Rich Gulch quartz has also interested them, and they have taken samples and made a thorough examination of the Hazzard property. They went through the Sunnyside mine, one of the old channel properties down the river from Seneca, and have become interested in the properties lying between the Glacier and the Sunnyside. The Glacier is being worked by San Francisco people, while good gravel is being mined at the Sunnyside.

After six years of unceasing effort, the long-sought gold-bearing channel in the Golden Ancient mine, near Quincy, has been intersected.

SACRAMENTO COUNTY

The Ashburton Mining Co. is negotiating for the purchase of the land and dredges of the bankrupt Union Dredging Co. The Ashburton company has little land left to work, and unless the deal for the Union property goes through, will complete operations within the next few weeks.

SHASTA COUNTY

(Special Correspondence.)—An inspection of the Cottrell electrical precipitating plant is under way. It is planned to experiment with this device in the tests to recover the sulphur from Balaklala ores at low costs. Residents of Redding have subscribed approximately \$5000 for the construction of a Fields process plant for treatment of copper ores without generation of noxious fumes. The building of the plant is planned for an early date. Numerous locations have been recently filed on the limestone deposits in the vicinity of Heroult. The limestone is of excellent quality, and strong interests are reported concerned in the acquisition of the deposits. The Noble Electric Steel Co. converts the material into an article of commerce by reducing the ores with the furnace gases from its electric iron furnaces. Including the June dividend of \$9000, the Hazel mine, at French Gulch, has disbursed \$54,000 in profits during 1913. This makes a total of \$954,000 to date.

Redding, July 21.

TUOLUMNE COUNTY

(Special Correspondence.)—The shaft at the Josephine mine, situated near the Shawmut, and bonded a few months ago to Mr. Lewis, of Stockton, and W. T. Jones, is 100 ft. deep, and from the bottom a cross-cut is being driven through the vein to the hanging wall. A drift will then be driven toward the north 100 ft., raising thence to surface, and subsequently sinking. The shaft now used will then be abandoned for the new one, which will contain three compartments, be larger, and better situated. Surface prospects show a shoot 800 ft. long and 150 ft. wide, assays returning from 50c. to over \$7 per ton. In the cross-cut being driven through the vein at a depth of 100 ft., assays show a better average. The mine is an old one, but has never been developed to any great depth, the present operators already having gone deeper than the former workings. It was once equipped with a Huntington mill, and a considerable tonnage of ore was mined, with good results.

W. T. Jones and J. McFarland have secured a lease on the No. 2 shaft of the Harvard and are working near the surface in ore that is paying well. The operators are confident of even better success in the near future. The hoist that has been installed on the leased ground is run by compressed air from the Harvard mine, as are also the machine drills.

Sonora, July 18.

YUBA COUNTY

The Hammonton company has bonded the Yuba river from Parks Bar bridge to the Narrows, and a boring machine will start work directly. This section is said to be rich in gold, as it is where the outlets from the Pactolus, Cement, Pittsburg, Blue Gravel, and Blue Point mines empty.

The Tarr Mining Co. has suspended operations at the old Blue Point property near Smartsville, after having spent many thousands of dollars on one of the most extensive mining plants in this part of the state. Apparently the investors, most of whom are said to be Sacramento people, have lost all they have put into the mine.

COLORADO

CLEAR CREEK COUNTY

The *Georgetown Courier*, in writing of the value of ore produced in the district in early days, quotes the following from the *Colorado Miner* of July 11, 1872. Figures were given by H. Stoelting, 'territorial' assayer for the county. This ore was shipped to Eastern states and Europe. The average assay value of 257 lots of ore was 298.6 oz. of silver per ton, valued at \$386.32. The several lots from which the samples were taken varied in weight from

a few hundred pounds to a number of tons, and aggregated about 500 tons. Included in these were 53 lots which gave an average yield of 42.2% of lead.

DOLORES COUNTY

It is stated that the Rico-Wellington mill has been temporarily closed. The mine will be kept in operation without interruption, the zinc ores to be stored until the mill is in readiness to resume. Shipments of lead and copper ores will be made without any interruption.

EAOLE COUNTY

It is stated that a vein has been found on the Wyoming and Beatrice claims which appears to be an extension of the Lady Belle. These two claims adjoin the Lady Belle claim to the northeast, and J. H. Hoffman, who is working these properties for Leadville men, states that the adit which is being driven on the Beatrice has cut a vein of low-grade ore like that found in the Lady Belle. The silver content is low, but it is understood that the vein is well defined and that its trend is toward the present workings of the Lady Belle.

OURAY COUNTY

During June, the Tomboy mill worked 28 days, crushing 11,500 tons of ore, yielding \$81,000 from cyanidation, and 1800 tons of concentrate was shipped. The profit was \$35,100.

During the quarter ended April 30, the Wanakah Mining Co. showed the following results:

Development, feet	583
Mill worked, days	87
Ore crushed, tons	4,174
Net value of crude ore, concentrate, and bullion...	\$35,868
Operating costs	22,691

Profit	\$ 13,177
Expenditure on improvements, etc.....	6,918

TELLER COUNTY (CRIPPLE CREEK)

The El Oro Mining & Milling Co. has issued a pamphlet dealing with its property and proposals for ore treatment. The Company owns 60 acres and has an option on 50 acres in the district. According to the report of R. L. Riggs, the best claims are on the north slope of Battle Mountain, and numerous veins and dikes cross them, as proved by surface work. About ten years ago the 500-ft. shaft was sunk and the adits were driven fifteen years ago. About \$1,000,000 worth of ore has been shipped from the property. There is now 500,000 tons of ore opened to 200 ft. which should be mined and milled at a profit of \$1 per ton. Tests on the ore show that, by simply crushing to 8 mesh and cyaniding, 85% recovery should be made. A 200-ton plant is recommended, to be erected on the hillside. A report by Linderfelt & Stewart practically confirms these figures. Recent development has opened 100,000 tons of ore. Tests on this ore showed the assay value to be \$12, and the tailing to be 20c. per ton after a 72-hr. leach on a 12-mesh product in a 3-lb. cyanide solution. The ore slimes readily, and will require classification, treating the slime independently of the sand. This will increase the extraction with little if any additional cost of treatment. A pocket of water, or a small watercourse, was opened on the 1600-ft. level of the Golden Cycle shaft last week, and in order to keep the electric pumps above water it was necessary to start up the steam pumps. Sinking of the Elkton shaft has been started from No. 12 level, and it is hoped to go 100 ft. before meeting with water.

The following description of the proposed El Oro mill is given by the *Cripple Creek Times*: It is favorably situated on the side of Battle and Squaw mountains in Eclipse gulch. Ores from the mines of the Company will be trammed to a storage-bin above the rock-crusher, and from this passes through a trommel, where a certain percentage of waste is rejected. The oversize from the trommel will be sent to the coarse-crushing rolls, and the fine rolls get that which passes the trommel. All ore is to be carried by a belt-conveyor to the main plant, where it is sampled and then run into storage-bins behind the Chilean mills. From one of these storage-bins that por-

tion of the oxidized ores amenable to direct cyanide treatment will be conveyed to a series of sand tanks, where the usual leaching process for extracting the gold will be used. From the storage-bins containing the sulphide ores, the material is fed uniformly by plunger feeders into the Chilean mills, along with weak cyanide solution. After being crushed, the ore flows to a distributing barrel, and then to concentrating tables. The product from these will be shipped to smelters. The pulp next is lifted by a belt and bucket elevator to classifiers, which make two products, sand and slime. Part of the former is reground in tube-mills, the balance being leached in vats. The reground pulp is elevated to a height sufficient to return it to the classifiers which separate from it and return to the tube-mills any sand that may have escaped being crushed fine enough in going through the mills the first time, while the slime classification flows to cone classifiers. The underflow of these goes back to sliming tables, the overflow to the dewatering tanks. The overflow solution separated from the pulp during the pulp-thickening process is pumped back to the mill service tanks for re-use in the Chilean mills and general mill service. The underflow of the heavier pulp particles separating from the charge passes to a series of Pachuca tanks. The pulp from these is finally filtered by a revolving machine, and gold is precipitated by either zinc dust or shaving.

IDAHO

CUSTER COUNTY

Active development and installation of machinery is to begin at the Wall Street mine, which contains both quartz and gravel. Salt Lake people are largely interested. Clarence E. Eddy also succeeded in getting Eastern people to supply money for the property.

LEMHI COUNTY

The compressor and engine-rooms of the American Development, Mining & Reduction Co., at Gibbonsville, were destroyed by fire that is believed to have been of an incendiary origin, on July 13. A slow-speed Chilean mill of 20 tons capacity will shortly be installed at the Dora quartz mine, owned by F. E. Gonder, on Sheep creek, adjoining the A. D. M. & R. Co.'s property at Gibbonsville. Assays taken from an adit recently driven through a 7-ft. vein show from \$13 to \$50 per ton. A ditch 2000 ft. long is being built which will furnish water-power to drive the mill.

SHOSHONE COUNTY

The outlook in the Coeur d'Alene region is encouraging, more men are employed in the mines and mills than ever, the production promises to be a record for the year, and mining operators and investors are being attracted to the district. Extensive development of the Laclede mine, lying between the Hercules and the Tamarack & Custer and adjoined on the north by the Interstate-Callahan, is being planned by the Company. The No. 2 adit is in 2200 ft., 1600 ft. of which is in a cross-cut to the lead, and the remainder a drift on the vein. The results in the bore were not satisfactory, and recently a shaft was started at a point in the adit 1800 ft. in from the portal. Crystallized lead, similar to that in the Hercules, is exposed in the shaft, and ore should soon be cut.

The hearing of the suit of the Bunker Hill & Sullivan Mining Co. v. the Caledonia Mining Co., an action in which the plaintiff company attacks the title of the Caledonia orebodies, on the ground of extralateral rights, will come up for hearing in the federal court at Coeur d'Alene on October 22. The annual meeting of the Snowstorm Mining Co. was held at Larson on July 29. The manager, Leo Greenough, stated that the geological conditions of the district have been carefully studied, and the indications are that the orebody cut off by a fault lies from 400 to 600 ft. below No. 4 adit-level and to the east. It is sinking from this level and believes there is a good prospect of finding the vein again. During the year the mill operated with good results. Good progress is being made with preparatory work for the National mill at Mullan. Net earnings of the Stewart Mining Co., near Kellogg, in

June were \$104,000. The shareholders in the Rex Mining Co., at Nine-Mile creek, are asked to subscribe \$30,000 for further mine development.

ILLINOIS

JO DAVIESS COUNTY

(Special Correspondence.)—The Mineral Point Zinc Co., which has purchased the old Marsden or Black Jack mine, south of Galena, has completed preliminary work and begun to pump out the mine. The Black Jack was worked on lease for many years by the Illinois Zinc Co. and has been a large producer. It is thought that changed conditions warrant reopening the property. The mining department of the Mineral Point company is about to move headquarters to Galena, so as to be in closer touch with the field. While prices for unroasted ore have been low for some weeks and a number of the smaller mines are idle, those equipped with roasting plants are doing well and some of the higher grades of ore are selling as well as ever. Buying is not active, as most of the smelting plants have a stock of high-priced ore to work off. The new plant of the American Lead & Zinc Co. at Hillsboro is settling down to regular work gradually. It began on low-priced Western ores, but is now using the higher grades from Wisconsin and some Joplin ore. Eventually it is expected that the new Tennessee mines will supply 300 tons per month to this plant.

Galena, July 19.

MICHIGAN

HOUGHTON COUNTY

The mining companies at Houghton and district will pay their employees semi-monthly after August 15. At the Quincy mine, a system of checking the miners as they go and return from underground has been adopted. Also, at several shaft-houses, comfortable new waiting-rooms have been provided. There were no startling developments in the strike during the week.

NEVADA

CHURCHILL COUNTY

During June, the Nevada Hills Mining Co. treated 4600 tons of ore, yielding \$59,012, with a net profit of \$28,181. The average recovery was \$12.83 and expenses \$6.70 per ton. Assets, including cash, supplies, concentrate, and bullion, and the metal in solution, total \$108,608, while bills payable are \$20,000. All indebtedness was expected to be liquidated during July.

ESMERALDA COUNTY

Rich gravel has been opened at Palmetto, near the border of California, by Grigsby and son, for 25 to 35 ft. width, and from 5 to 6 ft. of this the yield is from 50c. to \$1 per ton. An option has been taken by Goldfield people. Water is scarce.

NYE COUNTY

On July 14 a settlement was effected of the pending litigation between John F. Davidson and the Round Mountain Mining Co. by which the latter paid to the former

mont company shipped 179,324 oz. bullion on July 20, this being the clean-up for the first fortnight of the month. The quarterly report of the Tonopah Mining Co. shows that the mill recovery was \$643,967, and net earnings \$328,979. A dividend of \$400,000 was paid on April 21, and cash on hand on May 31 was \$382,528.

WHITE PINE COUNTY

The quarterly report of the Nevada Consolidated Copper Co. for the term ended June 30 was as follows:

Ore milled, tons	771,351
Value of copper	\$2,389,787
Mining cost	550,689
Transport of ore	203,366
Milling and smelting	1,360,747

Net yield\$ 274,985

The tax on this output amounts to \$5939.

Returns from 21 tons of ore from the Hamilton company's mine were 107.24 oz. silver, 20.55% lead, and 6.46% copper, netting \$1479. The owners of this property are mostly McGill men.

UTAH

JUAB COUNTY

It is stated that the option on 41 claims on Prospect mountain to Samuel Newhouse and Salt Lake City people will be completed within a few days. The old Dunderberg mines are included, and the shaft at the Atlas is to be retimbered to 500 feet.

High-grade lead ore has been cut on the 700-ft. level of the Eagle & Blue Bell, while the winze 90 ft. below the 1350-ft. level is in ore. At the Gemini, 100 men are working on leases. Some ore from this mine is averaging 320 oz. silver and 17% lead. Good carbonate ore has been opened on the 1000-ft. level of the Tintic Standard.

SUMMIT COUNTY

A new slime collector has been patented by R. V. Smith, of Park City, and a full-size machine is being installed at the Daly-Judge mill.

WASHINGTON

FERRY COUNTY

J. L. Harper, of the Harper Consolidated Mines, at Republic, has taken a bond on the Faithful-Surprise mine near Danville, and reports that the work is progressing rapidly and that the showing is encouraging.

STEVENS COUNTY

The Aurora and United copper mining companies, whose properties adjoin at Chewelah, are considering plans for extending the main adit of the latter into the former's ground to cut its veins at 1000 to 1500 ft. vertical depth. The United adit will have to be driven 3600 ft., and the Aurora adit is now in 1000 ft., having cut two veins of good ore. The latter adit is being driven 5 ft. per shift. Five cars of rich gold-silver ore have been shipped from the Union Mining & Smelting Co.'s mine, near Dunn. A 300-ft. shaft has been sunk and 400 ft. of cross-cuts driven.

MEXICO

JALISCO

The directors of El Favor Mining Co. have paid a dividend of \$35,000 on July 30, being 1c. per share on each share of outstanding stock. The political troubles in Mexico have not seriously interfered with the operations of the Company. While there have been some bandit raids in the state of Jalisco, the mines have been unmolested, and, while no lawless bands have visited the properties, it was deemed best to fortify the camp, and a high protecting wall with suitable defending towers has been built, surrounding the Company's principal buildings, and with the loyalty of the hundreds of men employed in El Favor and Mololoa mines adjoining, it is believed that operations are thoroughly protected now. Although the expense of erecting this fort will amount to several thousand dollars (full amount not yet known), it was deemed not only prudent but just to the loyal employees to give them every possible protection. Both the revolutionary and the gov-

PLAN OF IMPORTANT MINES AT TONOPAH.

and the parties interested with him, the sum of \$15,000 and 15,000 shares of treasury stock; and secured from him a release and satisfaction of the judgment of \$165,157.70; and a release of all claims of whatever nature now or at any time held against this Company. The directors have declared a dividend of 4c. per share, payable on August 25.

During the week ended July 26, the mines at Tonopah produced 10,800 tons of ore, worth \$255,110. The Bel-

ernment parties have done everything possible to protect the interests of the Americans, vying with each other in giving encouragement to foreign capital. If any interference occurs, it would be through the bandits. Vigorous development work is being continued, and in the Cande-

MAP OF MINING DISTRICTS OF JALISCO.

laria mines, being the farthest west workings of the properties, an unknown orebody has been cut which is proving quite extensive, carrying high bullion content.

SONORA

(Special Correspondence).—An English company has been granted a concession by the federal government for the construction of a railroad between Ensenada, Lower California, and Mexicali, on the border. The road is also to be continued east, crossing the Colorado river and traversing the northern part of Sonora to Magdalena, where it will connect with the Southern Pacific of Mexico lines. The road will be approximately 450 miles long, and will pass through some rich mining country, although for a considerable distance will be nothing but a desert waste, with no signs of habitation.

Sonora mines, especially those in the south and central portions, are seriously crippled by the inability to secure supplies. In the Tonichi neighborhood, almost all the mines have been closed down during the past month, including La Barranca, San Xavier, San Antonio Copper Co., and others that are of lesser importance. La Dura property of the Mines Company of America is still operating, but with a small force of about 60 men, and will probably be compelled to shut down by the end of July. Mina Mexico continues also, with about 100 men at work. The 85-ton smelter has been started and is using charcoal burned on the property as a substitute for coke. The result of the use of charcoal in the furnace is not yet known here.

San Ygnacio mine, situated in the Moctezuma district, has also been closed down, directly due to the present unsettled conditions. Funds have been exhausted and an effort is being made at present to secure sufficient funds to install a 100-ton mill and continue development work. Cananea, July 19.

The Tigre Mining Co. reports the June output as follows:

Ore crushed, tons	5,619
Tailing cyanided, tons	7,246
Bullion from shipping ore, concentrate, and cyaniding	\$133,049
Total costs	80,611
Profit	\$ 52,438

Since January 1, 1913, bonds amounting to \$117,750 have been purchased and cancelled. These purchases reduce the bonds outstanding to \$99,050.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

- E. H. NUTTER is in New York.
 - M. K. RODGERS is visiting New York City.
 - WALDEMAR LINDGREN is at El Oro, Mexico.
 - J. A. VAN MATER was in Wisconsin recently.
 - R. A. F. PENROSE, JR., was in San Francisco.
 - ARCHIBALD STARK is visiting Tucson, Arizona.
 - L. C. GRATON is spending the summer at Butte.
 - S. S. SORENSEN is at 165 Broadway, New York City.
 - DONALD F. IRVIN has returned to El Tigre from Los Angeles.
 - W. W. MEIN was in San Francisco and has returned to New York.
 - JOHN I. KANE is now at the Angangueo plant of the A. S. & R. Co., Michoacan.
 - PAUL S. COULDREY, mining engineer for the Cerro de Pasco, is at New York.
 - ARTHUR THACHER is examining the Potosi mine near Good Springs, Nevada.
 - P. B. SCOLLAND is general mine superintendent for the Arizona Copper Company.
 - T. W. H. SHANAHAN has been appointed superintendent of the San Francisco Mint.
 - W. B. CHIDESTER is with the Globe Consolidated Mining Co., at Dedrick, California.
 - ROBERT H. CHAPMAN is with the United States Geological Survey at Yerington, Nevada.
 - CLEMENT H. MACE is making an examination of the Amalthea mine at Smyrna, South Carolina.
 - BRITTON B. GOTTSBERGER has sufficiently recovered to resume his duties as manager for the Miami Copper Company.
 - A. E. KITSON passed through San Francisco on his way from Australia to Toronto to attend the International Geological Congress.
 - J. J. SHAW is superintending the first hydraulic placer installation in the Philippine Islands, for the Cansuran Placer Co., at Manila.
 - ALEXANDER WINCHELL, of the University of Wisconsin, is in charge of field work for the Oregon State Bureau of Mines with headquarters at Gold Hill.
 - E. B. TINKER is superintendent for the Superior & Boston, and W. A. SULLIVAN has been appointed chief clerk and purchasing agent to succeed the late Carlos W. Rice.
 - M. F. PERRY, resident director of Butters Divisadero Co. and Butters Salvador Mines, Ltd., Salvador, will be in Whitney's Point, New York, during August and September.
 - JAMES F. KEMP has been appointed chairman of the committee on mining geology of the American Institute of Mining Engineers, succeeding Waldemar Lindgren, resigned.
 - H. A. MORRISON has resigned as mine superintendent for the Uwarra Mining Co., at Candor, North Carolina, to accept a position with the Globe Consolidated Mining Co., at Dedrick, California.
- Among those who attended the excursion to Sudbury, Cobalt, and Porcupine, of the International Geological Congress, were the following: J. BARRELL, H. F. BAIN, A. G. BURROWS, JEAN CAILLEBOTTE, S. CERULLI-IRELLI, A. G. CHARLETON and Mrs. CHARLETON, A. A. COLE, G. A. J. COLE, A. P. COLEMAN, W. H. COLLINS, E. T. CORKILL, J. A. DRESSER, H. ECKFELDT and Mrs. ECKFELDT, Miss ANNIE EUBANK, F. H. FOREST, G. W. GRABHAM, P. E. HOPKINS, R. E. HORE, J. F. KEMP, C. W. KNIGHT, A. E. KITSON, A. C. LANE, E. LINDEMAN, E. MATTIROLLO, CHARLES McDERMID, BEDFORD McNEILL and Mrs. McNEILL, GUISEPPE MERCIAL, WILLET G. MILLER, L. J. MORIN, J. A. NOISEUX, OTTO F. PFORDTE, Miss C. A. RAISIN, F. L. RANSOME, L. REINECKE, W. R. ROGERS, HEINRICH SCHULZE, FRED SEARLS, W. E. SIMPSON, H. S. A. SJÖGREN, J. STANSFIELD, JULES SZADECKY DE SZADECSNE, J. B. TYRRELL and Mrs. TYRRELL, T. L. WALKER, EDGAR T. WHERRY, A. W. G. WILSON, and M. E. WILSON.

New York Metal Market Review

With all the metals is apparently a tendency on the part of consumers to carry no more stock than absolutely necessary. It is also evident that demand for finished products in brass and copper and some other metals has fallen off. Most of the metals were dull, and prices declined steadily in the early part of July, but an improvement in nearly all directions came toward the end of the month, though at the higher prices no great strength was shown. Copper had a good movement emanating from abroad. Lead prices alone remained fairly stationary. In spelter there were a couple of fair buying movements. Antimony and aluminum were dull, and prices of both declined without recovery. Tin was down to 39.35c. on July 9, and although a part recovery followed, prices are far below those of a few weeks ago.

COPPER

The Waterbury average for June was 15.37½c. per pound, or ½c. less than that of the preceding month. A dull market with quotations nominal at 15c. cash New York for Lake, and 14.62½c. cash New York for electrolytic, prevailed when the month opened. Consumers were well supplied and the demand for their finished products had fallen off noticeably. This latter fact explained the reduction of 1c. per pound in prices of copper and brass products which was announced July 1. The second week of July, Lake was down to 14.75c. and electrolytic to 14.50c., both cash New York, and there was talk of electrolytic at ½c. lower, with business still lacking. These were resale prices, as producers asked at least ½c. more. The June report of the Copper Producers' Association was looked for with anticipation, as the figures were expected to start buying. While the statistics were favorable in that they showed a decrease in stocks of 14,659,619 lb., they were unfavorable in showing a falling off in domestic consumption of about 12,600,000 lb. as compared with May, while the exports were a trifle less also. Production in June fell off nearly 19,500,000 lb. as compared with May, for which the strike at the Nichols refinery on Long Island was largely responsible. The large shrinkage in stocks was not expected. The world's total visible supply of copper at the time of the report was 61,815 gross tons, the lowest on record since the publication of the Association's reports. The lowest previous stock was at the end of June 1912, when the figures were 67,931 tons. So far as inducing business was concerned, the report was disappointing, and the second week of the month brought no improvement. Prices declined and, on July 15, 14.12½c. cash New York was the quotation for electrolytic, with Lake nominal at 14.50c. cash New York. The declines were attributed entirely to lack of business. On July 18 there was a turn for the better, and 14.25c. cash New York was quoted for electrolytic, and this was advanced July 21 to 14.37½c. On July 24 the largest producing interests advanced their asking price to 14.62½c., f.o.b. New York, or 14.75c. cash 30 days. The improved prices began with good buying abroad, some reports stating that as much as 75,000,000 lb. was taken by foreign consumers, though many regarded this figure as excessive. Allegations were heard that the buying had been artificially stimulated to secure action on the part of the consumers before the publication of the July report of the Copper Producers' Association; but, whatever the cause, there was good buying in England, France, and Germany, followed by a fair movement in this country. The domestic buying was not extremely large, as consumers distrusted the situation and were buying no more than was necessary. Early shipment copper was not easy to obtain at this time, partly as a result of the trouble at the Nichols refinery. Up to July 25, inclusive, exports totaled 19,375 tons.

The producers and leading agencies on July 25 raised their quotation for electrolytic to 15c., 30 days, delivered, or 14.87½c. cash New York. Because of the better tone, copper wire in carload lots at the mill was advanced ½c. to 16½ cents.

LEAD

The New York price of this metal was stationary at 4.35c., but at St. Louis there was at times a premium of 2½ points over the price of 4.20c. On July 1 lead was dull, though quotations were firm, with 4.22½c. quoted at St. Louis. This last quotation declined to 4.20c. within a few days, as demand was light and complaint was heard from consumers that their business was falling off. About the middle of July, however, better inquiry developed, and it became apparent that consumers had let their stocks become low, a condition noted in the case of many raw materials and traceable to a disposition to let 'the other fellow' carry the stocks. Buying was done most cautiously. On July 18, some buying worthy of note again started, but it tapered off as soon as the immediate needs of consumers were covered. It left the St. Louis price higher again at 4.22½c. On the whole, the month was not satisfactory.

SPELTER

Good inquiry was in evidence July 1, with 5.30c. New York and 5.15c. St. Louis quoted. In June, prices had been considerably lower. In the first few days of July, more spelter was sold than had changed hands in many weeks previously. On July 8, 5.40c. to 5.50c. New York, and 5.25c. St. Louis, were quoted. Business was good in both prompt and future delivery metal. Consumers' stocks were being replenished after reaching a low ebb. About the middle of the month, the demand having been satisfied, business tapered off again and quotations dropped to 5.30c. New York and 5.15c. St. Louis. About July 21, however, there again was improved inquiry, with a corresponding stiffening of prices, and by July 23 quotations were again 5.40c. New York and 5.25c. St. Louis. The buying was mostly for prompt delivery, confirming again the low state of consumers' stocks.

ANTIMONY

Only such adjectives as dull, stagnant, and neglected have been used in any part of July in describing the state of the market for antimony. July opened with quotations at 8.50 to 8.60c. for Cookson's, 8c. for Hallett's, and 7.50 to 7.60c. for Chinese and Hungarian grades. Near the close of the month, 8.40 to 8.50c. was quoted for Cookson's, 7.75 to 8c. for Hallett's, and 7.25 to 7.50c. for Chinese and Hungarian.

TIN

July started in weak at 41.60c., there having been a gradual decline in the latter part of June. The low price caused a fair demand for small lots from consumers who needed only a few tons and took advantage of the slump. Most of them, however, were sufficiently supplied for July. Incidentally, many of them had paid as high as 48c., or even higher, for the metal they were using. On July 3 there was a flurry in which about 200 tons was sold to dealers who did not wish to remain uncovered on short contracts over the Independence Day holiday. On July 7, the first real business day after the holiday, tin sold at 40.20c., and by July 9 it had dropped to 39.35c., as against 51.12½c. a few months ago. In London, prices had been most erratic, which, of course, was nothing new. But a comparison is almost startling. The quotation in London, July 9, was £178 for spot, while the highest price of the year was £232, thereby making a difference of £54, equal to a decline of about \$250 per ton. July 10, with the market at 39.55c., a fair business was done, consumers taking about 250 tons. The London market then showed a higher trend and on July 16 was £5 higher than on July 9. Toward the latter part of the month a better demand appeared, especially for spot and early shipment, showing again that small stocks were being carried by consumers. London continued to advance, and the price in New York on July 23 was 42c., and on July 24 it came down to 40.85c. World statistics available at the beginning of July showed the total visible supply on June 30 to be 11,101 tons, or 1819 tons less than that of June 30, 1912. June deliveries into domestic consumption were 3800 tons. The total domestic deliveries for 6 months of 1913 showed a decrease of 550 tons as compared with the same time a year ago.

The Metal Markets

LOCAL METAL PRICES
San Francisco, July 31.

San Francisco is not a primary market for the common metals except quicksilver. The prices quoted below therefore represent sales of small lots and are not such as an ore producer could expect to realize. Ore contracts usually call for settlement on the basis of Eastern prices, less freight and treatment charges. The prices quoted are in cents per pound, except in the case of quicksilver, which is quoted in dollars per flask of 75 pounds.

Antimony.....	12-12½c	Quicksilver (flask).....	\$41
Electrolytic Copper.....	16-16½c	Tin.....	50-51½c
Pig Lead.....	4.75-5.70c	Spelter.....	7-7½c
Zinc dust, 1400 lb. casks, per 100 lb., small lots \$9.50-9.75; large \$7.50-8.50			

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

COPPER SURPLUS

Figures showing the visible supply of copper at the beginning of each month are now widely available. Below are given the amounts, in pounds, known to be available at the first of each of certain months. The figures are those of the Copper Producers' Association supplemented by Merton's figures of foreign surplus.

	U. S.	European.

The fortnightly statistics of copper show that the European stocks, including Hamburg and Rotterdam, on June 30 decreased 1727 tons, while copper supplies afloat decreased 50 tons, making a total decrease in the visible supply of 1777 tons to 38,199 tons, as compared with 39,976 tons on June 14 last.

QUICKSILVER

The primary market for quicksilver is San Francisco, California, being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

Week ending	July 17.....

ALUMINUM

Early in July, quotations declined ½c., making the price 23 to 24c. for prompt-shipment domestic metal. The foreign product, in bond, was quoted at 18.50 to 19c.

is little to say of aluminum except that the market was dull all through the month, with proposed tariff changes pointing to lower prices. Toward the middle of the month the range for domestic changed to 23 to 23.50c., and foreign, in bond, to 18.50 to 18.75c. The market steadied a little in the last week of July.

COPPER production of the Wolverine Copper Mining Co., during its fiscal year ended June 30, was 8,350,000 lb. The average per ton of 'rock' stamped was 21½ lb. copper.

GOLDFIELD CONSOLIDATED REPORT

During June, according to the general manager, Albert Burch; the total production was 30,486 tons, which resulted in a net realization of \$180,782, of which the mining realization was \$57,004, and milling and transportation, profit and miscellaneous earnings were \$123,777. Costs per ton were as follows:

Mining.....	\$2.69	Construction.....	0.06
Development.....	0.65	Marketing ore shipped.....	0.98
Moving dumps.....	0.02		
Transportation.....	0.09	Total costs.....	\$6.79
Milling.....	1.91	Miscellaneous earnings.....	0.03
Marketing.....	0.05		
General expense.....	0.28	Net costs.....	\$6.76
Bullion tax.....	0.06		

Development work covered 3323 ft. during the month, at a cost of \$5.99 per foot.

On the third level of the Combination, about 100 ft. east of the shaft, the 201-C sill was cut and produced 285 tons of \$7 ore. The 414-D winze was continued to a depth of 100 ft. below No. 6 level, where a station was cut and cross-cutting commenced.

On the new No. 1 level of the Mohawk, the 3-R sill was extended and produced 395 tons of \$15 ore. On No. 1 level, the 170-BX sill was extended and produced 281 tons of \$10 ore, and about 100 ft. farther to the northwest the 170-CX sill was started and produced 204 tons of \$15 ore. The ground between these two sills will probably pay to stope. The 205-GY sill on No. 2 level, about 400 ft. northwest of the shaft, was commenced, and produced 309 tons of \$16 ore. A considerable amount of preparatory work was done during the month for the purpose of beginning to re-stope the old Truett and Francis-Mohawk lease stopes above No. 2 level, southeast of the shaft.

On the second level of the Laguna, about 600 ft. south of the shaft, the 241 drift is following a streak of ore which is farther toward the hanging wall than anything discovered above or below. It produced 103 tons of \$8 ore and is improving in grade as it advances. Diamond-drilling has been commenced for the purpose of exploring the vein below the bottom level of the Laguna.

The 901-E sill of the Clermont-Jumbo was extended and produced 350 tons of \$14 shipping ore.

COPPER IN LONDON

Electrolytic copper was quieter on July 29, but there was a big demand for manufactured copper. The Amalgamated agency quotes £69 10s. (15½c.) for electrolytic for August and £69 12s. 6d. for September; American Smelting, £69 15s. for September and October; Phelps, Dodge & Co., £70 for October.

THE ABANGAREZ GOLD FIELDS of Costa Rica reports the following yield during May:

Ore crushed, tons.....	5,663.0
Tailing leached, tons.....	425.5
Slime treated, tons.....	4,748.0
Extraction by amalgamation.....	\$12,263
Extraction by cyanidation.....	29,450

Total extraction.....	\$41,713
Cost of operation, marketing and administration (Exclusive of betterments).....	57,441
Profit from operations.....	*\$15,727
Betterment expenditures.....	\$5,641
*Deficit.	

United States Steel earnings for the past quarter netted \$41,219,813, against \$34,426,801 in the March 31 quarter, and \$25,102,265 in the June 30, 1912, quarter. The net earnings by months in the past quarter were as follows: April, \$13,072,701, increase \$5,563,583; May, \$14,554,566, increase \$5,707,744; June, \$13,592,537, increase \$4,846,300.

THE Granby Smelting Co. treated 22,721 tons of ore at its smelter at Grand Forks, British Columbia, during the seven days ended July 21. Of this, 741 tons was custom ore, and the blister copper shipments were 347,000 pounds.

Current Prices for Ores and Minerals

(Corrected monthly by Atkins, Kroll & Co.)
The prices are approximate, subject to fluctuation, and to variation according to quantity, quality, and delivery required. They are quoted, except as noted, f.o.b. San Francisco. Buying prices marked *.

Industrial Materials of California

Advance data from the annual report of 'Mineral Production of California,' by the State Mining Bureau, San Francisco, show the following:

The mineral industry of this state falls naturally into five general divisions: fuels, metals, structural materials, industrial materials, and salines. The value of the industrial materials produced is a small portion of the total mineral output of the state; nevertheless, these substances are attracting more attention every day and show a steady growth from year to year. The following minerals comprise the list: Asbestos is found widely distributed; barytes is found principally in Mariposa and San Bernardino counties; clay and feldspar are produced in many localities; fullers earth comes from Kern and neighboring counties; gems are mined in great variety in San Diego, Tulare, Los Angeles, and Siskiyou counties; gypsum is widely distributed in the desert regions of the state; infusorial earth comes largely from Monterey and Santa Barbara counties; limestone occurs in practically every county in the state; manganese production is nominal to date; mineral paint in numerous deposits is only partly developed; mineral water is one of California's best known products, although the exploitation of the mineral springs of the state is even yet in its infancy; pumice occurs commonly in the southeastern part of the state; pyrite, a constituent of many ores, some of which is utilized in the manufacture of sulphuric acid, and glass sand and soapstone.

The amount and value of these minerals marketed in California during 1912 is given in the following table. Value is for the crude material at the property.

Substance.	Quantity, tons.	Value.
Asbestos	90	\$ 2,700
Barytes	564	2,812
Clay	199,605	215,683
Feldspar	1,382	6,180
Fullers earth	876	6,500
Gems		23,050
Gypsum	37,529	117,388
Infusorial earth	4,129	17,074
Limestone	573,282	570,248
Manganese	22	400
Mineral paint	300	1,800
*Mineral water	2,497,794	529,384
Pumice	100	2,500
Pyrite	69,872	203,470
Sand glass	13,075	15,404
Soapstone	1,750	7,350

Total value\$1,721,943

*Gallons.

Metal Output of Idaho

The value of the mine output of precious and semi-precious metals in Idaho in 1912, according to C. N. Gerry, of the United States Geological Survey, was \$21,466,521, against \$19,100,894 in 1911.

The production of gold was valued at \$1,381,214, only slightly more than in 1911. The yield from deep mines was about \$220,000 less in 1912 than in 1911, but the yield recovered by dredging and other placer-mining methods was \$228,000 larger. The silver output was 8,294,745 oz., an increase of less than 1%. About 84% of the silver yield was derived from lead ores and 6% from lead-zinc ores.

The production of copper increased from 5,152,937 lb., valued at \$644,117, in 1911, to 7,492,152 lb., valued at \$1,236,205, in 1912, although the Lost Packer smelter was not operated. The lead production in 1912 was 284,185,657 lb., valued at \$12,788,355, an increase of 11,629,132 lb. Record shipments of zinc ore and concentrate were made in 1912 when the production of zinc was 13,905,502 lb., valued at \$959,479. The increase of 5,565,253 lb. was due mainly to larger shipments of concentrate from the Success and Morning mines.

Of the 408 producing mines in Idaho, 173 were deep mines which shipped or treated 2,266,334 tons of ore, an increase of 95,437 tons compared with 1911. Of this ore tonnage sold or treated, 1,985,517 tons were concentrated, 193,823 tons were shipped crude to smelters, and 82,568 tons were treated at gold and silver mills. Shoshone county, or the Coeur d'Alene region, produced metals valued at \$18,314,604. This important region produced 6% of the gold, 90% of the silver, 59% of the copper, 93% of the lead, and nearly all of the zinc reported by Idaho mines in 1912.

Metal Output of Montana

Great strides were made by the state of Montana in 1912 in the production of gold, silver, copper, lead, and zinc, according to W. C. Heikes, of the United States Geological Survey, the value of the output being placed at \$64,754,613, against \$46,955,287 in 1911, an increase of \$17,799,326, due to the greater production and higher value of copper. Most of this increase—\$17,798,698—may be credited to the production of Silverbow county, which includes the Butte district. The combined production of the other counties in Montana was only \$628 greater in 1912 than in 1911. The value of the silver, copper, and lead production combined was \$18,524,437 more than in 1911, while the value of the gold and zinc was \$725,111 less than in 1911.

Production of gold was valued at \$3,625,235, against \$3,710,751; silver, 12,731,638 oz., valued at \$7,829,959, against 11,985,196 oz.; lead, 7,446,749 lb., against 6,431,575 lb.; and zinc, 26,918,881 lb., against 43,810,145 lb. in 1911.

The number of deep mines producing metals in Montana in 1912 was 452, against 430 in 1911, and the number of producing placer mines was 152, against 180. The total quantity of ore sold or treated was 5,552,164 tons, and the total average recoverable value per ton of ore produced increased from \$9.36 in 1911 to \$11.52 in 1912.

The production of copper increased from 272,847,705 lb. in 1911 to 309,738,873 lb., valued at \$51,106,914, in 1912, a gain of 36,891,168 lb. The Summit Valley or Butte district contributed all but 1,516,326 lb. of the total.

Silver Statistics

*During the first six months of the current year the imports of silver bullion to England amounted to 62,457,666 oz., a total remarkably close to that of the imports during the first six months of 1912, namely, 62,682,782 oz. Though the total is similar, the proportions furnished by contributing countries differ considerably. For instance, the United States is credited with 3,800,000 oz., Mexico 800,000 oz., and Germany 600,000 oz. less, but Canada about 5,000,000 oz. more. It must not be inferred from the

*From Report of Samuel Montagu & Co., London.

above that the production of Canada has increased to a corresponding degree. The reason for larger figures from that quarter is that a great deal of the silver refined formerly in the United States is now treated in Canada itself. One interesting deduction to be made from these figures is that the undoubted sparsity of supplies, which has been felt during the past month or so, has been compensated for by larger arrivals in the earlier months of the year. Possibly, the comparatively high prices which then ruled led to freer sales than at the lower level of prices which now obtains.

The exports during the first six months of this year are 5,000,000 oz. less than in the corresponding term of last year. The total, 48,186,027 oz., is over 14,000,000 oz. less than the imports, implying an increase in the London stock of £1,750,000.

Exports to China were less by 5,000,000 oz. and to India by 4,000,000 oz. An active coinage demand for the Continent made up a portion of this deficit, and was composed of 1,100,000 oz. for Russia and 1,000,000 oz. for Germany, more than during the same period last year, in addition to an unusually large minting order of 3,700,000 oz. for Holland, mostly for its East Indian possessions.

A shipment of £45,000 was made from San Francisco to Hongkong.

Public Lands Reopened for Entry

Six million acres of withdrawn public lands were restored to entry during the months of May and June upon approval by the Secretary of the Interior on the recommendations of the United States Geological Survey. This action was the result of examination and classification of the lands by the Survey, those restored either having been found not to be valuable for power-sites, reservoirs, coal, phosphate, or potash deposits, or having been definitely valued as coal lands, and rendered available for purchase under the coal-land law.

Of these lands relieved from coal withdrawal, nearly 2,500,000 acres were in the state of Colorado. Five thousand five hundred acres were also withdrawn in Colorado as water-power sites. In Idaho 1,100,000 acres of coal and phosphate withdrawals were classified and restored, and for water-power sites approximately 10,000 acres were withdrawn, and about the same acreage restored. In Montana, 250,000 acres were restored as being non-coal bearing, and about 1000 acres as not valuable for water-power sites, while about 150 acres were withdrawn for that purpose. In North Dakota, nearly 1,400,000 acres in coal withdrawal were classified and restored. In Oregon, approximately 75,000 acres were restored as non-oil-bearing lands, and about 12,000 acres were withdrawn for water-power or reservoir sites. In South Dakota over 330,000 acres were relieved from the coal withdrawal. In Utah about 1500 acres were withdrawn for water-power sites. In Wyoming, over 47,000 acres of coal withdrawals were reopened to entry and purchase; approximately 87,000 acres were withdrawn for classification as to whether they are oil-bearing lands, and about 304,000 acres were restored as non-phosphate lands.

For all states the total withdrawals during the months of May and June were over 116,000 acres, and the total restorations were over 6,000,000 acres. The total outstanding withdrawals on July 1 in all the public-land states amounted to 68,609,289 acres, of which more than 58,000,000 acres are in coal-land withdrawals. These lands are held pending classification by the Survey, and as rapidly as they are found to be mineral bearing they are either valued and placed on sale (as in the case of coal lands), definitely reserved pending appropriate legislation by Congress to provide for their disposition (as in the case of potash or phosphate lands), or held subject to development under departmental regulations (as in the case of water-power or reservoir reservations); or if they are found to be non-mineral in character, they are restored to public entry. This work of classification and valuation is being conducted by the Survey as rapidly as the appropriations provided by Congress will permit.

Company Reports

WEST END CONSOLIDATED MINING COMPANY

This Company operates at Tonopah, Nevada, and the property consists of 158.37 acres of patented and 25.70 acres of unpatented claims, as well as a 20-stamp mill and cyanide plant. The report covers the year ended March 31, 1913, and that of the general manager, S. H. Brady, contains the following information.

Development work, consisting of drifts, cross-cuts, raises, shaft-sinking, and winzes, covered 5859 ft., at a cost of \$49,591. The result of operations during the past year has been of a more satisfactory nature than were those of the previous year. At the time the last report was written, the south vein had already been discovered in the West End claim, and raising and stoping had been started. During the past year, most of the ore produced has come from the south vein above the 500-ft. level, to the west of the shaft, with the exception of a small amount of ore which has been extracted from above the 400-ft. level. The 500-A, 500-B, and 500-C stopes have produced the necessary amount of ore to keep the mill in constant operation.

During the year the shaft was sunk to the 600-ft. level, and a cross-cut driven to the south to cut the extension of the big stopes on the south vein, known as 500-A. After cross-cutting and driving a considerable distance, this has been accomplished. Drifts have been driven both east and west from the main south cross-cut on the 600-ft. level, and a winze was sunk from the 500 to the 600-ft. level, to the east of the shaft. This winze has practically been in continuous milling ore for its entire depth and gives a total back of 288 ft. of ground on the dip of the vein above the 600-ft. level.

To the west of the main cross-cut, connections have been made with the 550-ft. intermediate level by a series of three raises, and stoping ore is in progress from, and above, these raises. At the 550-ft. intermediate level, a vertical fault has disturbed, and thrown the vein to the south. A south cross-cut has picked up the vein 150 ft. south of the main west drift, which practically assures a considerable quantity of ore for some time to come; but owing to the small amount of development done so far, it is impossible to make an accurate estimate of tonnage, which is also the case in the balance of the workings. Therefore no effort has been made to estimate tonnage in sight.

The shaft was sunk to the 800-ft. level, where a north-west cross-cut has been driven to connect with the 800-ft. level of the MacNamara Mining Co., which was driven from the shaft to the west end-line, in what is known as the lower contact vein. This work was completed on April 23, 1913, an air connection having been made, and the vein cut as expected at this point, showing a width of 18 to 20 ft., with a pay-streak of milling ore 4 to 5 ft. in width.

Experience has shown that, in order to find ore in the West End mine, cross-fissures and faults must be found. These are pre-mineral faults, and are unquestionably the source of mineralization in this particular part of Tonopah. In driving on the veins, as these faults are approached, the metal content improve, and on the junction of the faults and cross-fissures with the veins, are found the best assays. As driving is continued through the faults, they gradually diminish until close to another fault, when they increase again.

That part of the West End claim which contains the lower contact vein just cut, is badly faulted and crossed by many north and south cross-fissures, and development should prove the lower contact vein to be a large producer of fair-grade milling ore. However, this is mere surmise, as the work of development has not yet been done. The first assay from this vein, taken on April 24, was \$11.45 per ton, across a face of four feet of ore, with no attention being paid to the high-grade contained in the vein. This vein crosses the side-line at a point 500 ft. east of the northwest corner of the West End claim, and has a strike south 23°, with a dip of 25° to the southeast. This vein, projected on its dip, should be cut by the shaft at a depth of 960 ft., and as soon as sufficient development has been done on the lower

contact vein to demonstrate its worth, it is recommended that the shaft be sunk to this point, which would give approximately 300 ft. of backs on the slope of the vein.

Before sinking to 960 ft., it will be necessary to install a new hoisting engine, the small hoist now in operation having reached its limit, and is, in fact, at present badly overloaded. The new one should be good for 1200 to 1500 ft. vertical depth, and capable of handling at least a two-ton skip at from 800 to 1000 ft. per minute.

The ore-shoot above the 500-ft. level in 500-A stope, has been proved to be of a total length of over 300 ft., and has also been partly developed by a winze below the 500-ft. level, which proves ore for a depth of 100 ft. on the vein. The downward continuation of 500-B ore-shoot to the east of the shaft has not yet been cut by the east drift on the 600-ft. level. The most easterly ore-shoot, known as 500-C, has been proved by the above mentioned winze to go down for a total depth of at least 288 ft. This ore-shoot is over 200 ft. in length, and the winze partly proves a block of ground 200 by 300 ft., by an average of at least 12 ft. in width, all of a good milling grade, and later, in cross-cutting from the bottom of the winze, 4 ft. of \$100 ore has been cut on the hanging wall side of this big vein.

The value of new equipment added to the property totaled \$28,480, which included a Leyner drill sharpener, engine house, shaft repairs, 5-ton Pierce-Arrow auto-truck, electric equipment, and hoist, air-compressor of Nordberg manufacture. Other properties were examined and two properties in the Yerington copper district were acquired.

The financial results were as follows:

Ore treated, tons	44,756
Gross value	\$770,876
Revenue from bullion, loan, etc.	675,599
Balance at April 1, 1912	27,489

Total revenue	\$703,088
Expenditure on mining, treatment, loans, property, etc.	524,662

Balance at March 31, 1913	\$178,426
Assets, consisting of cash, shares, bullion, property, etc.	707,459
Liabilities	35,135

COLORADO MINING COMPANY

This Company is operating in the Philippine Islands, and has a capital of 100,000 shares, with a par value of ₱10 each. The report covers the year ended December 31, 1912. During the term, general conditions of the properties improved, the mill was in continuous operation, and development of the mine continued uninterruptedly, while roads were constructed and suitable houses erected for employees. Ore is being supplied by the main orebody, and No. 1 and No. 2 levels have been extended, and the mine is capable of producing all the mill can handle. Development covered 2182 ft. Ore reserves total 217,215 tons, averaging \$10.77 per ton, equal to \$2,388,885. The stamp-mill operated 293 days, crushing 113.2 tons per day. Operations may be summarized as follows:

Ore treated, tons	33,169
Extraction, per cent	89.84
Gold and silver production	\$340,515
Mining, milling, general, development expenses....	182,527
Profit	\$161,988
Capital expenditure	29,993
Reserve for depreciation	33,825
Interest on convertible notes, 11 months.....	4,583
Dividend	50,000

Gold production of Rhodesian mines in June was as follows:

	Tons.	Value.	Profit.
Chartered & General.....	2,062	\$18,000	\$8,000
Giant Mines	11,462	60,000	25,000
Globe & Phoenix.....	6,450	210,000	135,000
Lonely Reef	5,146	62,000

The St. John del Rey Mining Co., Brazil, in June treated 13,830 tons of ore yielding \$153,000.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

ASBESTOS has been used in recent years as a filler for high-grade paints.

ASPHALT CONTENT of oil from 56 wells at Coalinga, California, averaged 26.5 per cent.

IRON ORE PRODUCTION of the Harz mountains, Germany, was 17,852,571 metric tons in 1912.

COAL was known to exist in the Richmond basin of Virginia in 1700, while it was mined in 1750.

WIRE-NAIL PRODUCTION in the United States in 1912 amounted to 14,659,700 kegs of 100 lb. each, against 13,437,778 kegs in 1911.

PIG IRON PRODUCTION of the United States in June was 2,628,565 tons. At the beginning of July there were 285 furnaces in blast.

ASBESTOS production in the United States in 1912 was 4403 short tons worth \$87,959. That from Canada was 131,260 tons worth \$2,979,384.

IMPORTS of petrol into Great Britain in 1912 amounted to 80,000,000 gal., of which the Dutch East Indies and United States supplied 46,000,000 and 16,000,000 gal. respectively.

CONCENTRATE at the West End mill, Tonopah, averages 1.80 oz. gold and 408.5 oz. silver per ton. Assays at this mill cost 18c. per assay, and refining bullion costs 0.47c. per ounce.

MERCHANTABLE saw timber standing in the United States is estimated to total 2,826,000,000,000 ft., which, divided by the annual lumber output of 40,018,282,000 ft., gives a supply for about 70 years.

DEVELOPMENT work at the West End mine, Tonopah, during 1912 cost as follows, per foot: driving, \$6.50; cross-cutting, \$6.44; raises, \$6.66; winzes, \$13.39; and shaft-sinking, \$27.73 per foot.

ANALYSES of gypsum from various states ranges from 0.10 to 9.37% SiO_2 , 0.08 to 0.78% Al_2O_3 and Fe_2O_3 , 0.25 to 4.32% CaCO_3 , trace to 0.35% MgCO_3 , 68.29 to 79.26% CaSO_4 , and 16.88 to 20.96% H_2O .

TIN EXPORTS from the Dutch East Indies, in 1912, were as follows: Banca island (government), 15,446 tons; and Billiton island (private), 1766 tons, a total of 17,212 tons, against 16,005 tons in 1911.

ROCK-DRILLING CONTESTS at Valdez, Alaska, resulted in M. J. Callaghan and son covering 37½ in., Hill and Lundstrom 34 in., and Whalen and Johnson 33½ in., through hard granite in 15 minutes.

AN OXY-ACETYLENE BLOWPIPE, with two or three jets, playing on the hard scale in a boiler, will make it crack off, due to rapid expansion of the scale. The jet should not be directed onto the bare plate.

QUICKSILVER production of California from 1850 to 1912 totaled 2,124,732 flasks, valued at \$95,275,695. The price has decreased from \$99.45 to \$42.05 per flask during that time, save in 1874, when it averaged \$105.18 per flask.

BULLION AND MONEY stored in vaults of the Denver mint on July 1, 1913, was valued at \$493,712,787.13. This is the greatest amount of wealth accumulated in any one place in the United States, and one of the three largest amounts at any one place in the world.

DAEDGED GROUND at Oroville, California, is responsible for the first shipment of tokay grapes of the present season,

being seven days ahead of last season. The reclaimed land is owned by J. H. Leggett, who has made a particular study of growing fruit on this so-called debris.

RESIDUE from tin-dressing plants in Cornwall, England, is being treated by a tailing company, which, during its past fiscal year, treated 78,885 tons of residue at an average cost of \$1.10 per ton. The net profit was \$86,000, and reserves to be treated amount to about 1,000,000 tons.

PHOSPHATE DEPOSITS of Decatur county, Tennessee, are found in and at the top of the Decatur limestone, of Silurian age. The limestone is very pure, and the phosphates occur in irregular thicknesses, from a few inches to 20 or 30 ft. Analyses show 25.90 to 34.49% P_2O_5 (phosphoric acid). Transport is afforded by railway nearby.

THE new ore-shoot on the 1170-ft. level of the Tonopah Merger is composed of solid black sulphide, and an interesting geological fact is that the vein is out of the contact of West End rhyolite and Montana breccia, in which it occurred on the level above, and is now a fissure vein in the breccia, the oldest formation in this section of the Tonopah district.

LIQUID AIR, and more especially liquid oxygen, is being experimented on in Germany as mine explosives, according to *Echo des Mines*. The latter, mixed with aluminum powder, and detonated, forms an explosive about 2½ times as powerful as black powder, from which there can be no deleterious fumes, as the only products of an explosion are oxygen and alumina.

COAL MEASURES of Queensland cover 73,000 square miles, as far as geologically surveyed, the area of the state being 670,500 square miles. The formations containing coal are (1) Upper Cretaceous, (2) Trias-Jurassic, and (3) Permo-Carboniferous, the second named producing the present output. The percentage of fixed carbon varies from 41.0 to 80.1%. Total production to the end of 1911 was 13,251,883 tons.

AN AERIAL TRAMWAY, 13 miles long, is now conveying salt from the deposits of the Saline Valley Salt Co., of Inyo county, California, to the railway at Swansea. The Company owns 1400 acres of salt-producing ground in the valley. The tramway is made up of five sections, each working independently of the other, and electrically driven. Buckets hold 700 lb. of salt each, and cross the mountains at an elevation of 8700 ft. The capacity of the line is 20 tons per hour, and construction work was started in April 1911. Mules were previously employed in hauling wagons from the deposits.

THE geographical distribution of shafts will give some idea of the immense area of the German potash field: Province of Saxony, 54; Province of Hanover, 34; Duchy of Anhalt, 9; Grand Duchy of Saxe-Weimar, 7; Alsace, 5; Principality of Schwarzburg-Sondershausen, 4; Province of Hesse-Nassau, 4; Duchy of Brunswick, 4; Duchy of Saxe-Meiningen, 2; Principality of Schwarzburg-Rudolstadt, 1; Duchy of Saxe-Coburg-Gotha, 1; and Grand Duchy of Mecklenburg-Schwerin, 1. The German government estimated that the potash production during the fiscal year 1912 would be 1,131,900 short tons.

DRAWN TUNGSTEN FILAMENTS are found to have an entirely different structure from those prepared by reduction of the oxide, the former being fibrous, while the latter are granular. Examination of the filaments, after burning in lamps for 500 hours, with either a continuous current, producing a temperature of about 1900°C., or an alternating current of 42 cycles, shows that in both cases the metal is transformed into the micro-crystalline condition, just as has been previously shown to occur with the old filaments produced from the oxide, according to O. Scarpa. Drawn tungsten filaments should, therefore, be much more durable than drawn tantalum filaments, which form larger crystals under the combined action of temperature and vibration.

Decisions Relating to Mining

Specially reported for the MINING AND SCIENTIFIC PRESS.

MINER'S INJURIES—EMPLOYER NOT NEGLIGENT

An employer is not negligent in failing to instruct a miner engaged in blasting how long to remain away after an explosion, where the miner had had some months' experience and knows how long he should remain away.

Stanich v. Pearson Mining Co. (Minnesota), 141 Northwestern, 1100. May 29, 1913.

NO TITLE TO LAND IN OIL LEASE

A grantee under an oil and gas lease of the right to prospect for, extract, and appropriate the minerals together with the right to surface land necessary for such purposes has no such interest in either land or minerals as will entitle him to maintain ejectment thereon, until he goes into possession under his lease. An oil and gas lease is a grant of an incorporeal hereditament, and no title vests in either the oil or the gas until the same is reduced to possession by extraction.

Priddy v. Thompson (Oklahoma), 204 Federal, 955. April 25, 1913.

EXTRALATERAL RIGHTS—INJUNCTION DENIED

Where the owner of the apex of a vein claims extralateral rights thereon beyond his surface boundaries drawn vertically downward, he will not be granted an injunction *pendente lite* against the owner of the surface under which the orebodies in dispute are situated, who for many years has openly and notoriously mined such orebodies, on a mere averment in the bill of complaint that the apex-owner is in possession of the extralateral rights by virtue of being in possession of the apex. The remedy of the owner of the apex lies in ejectment not in equity.

Golden Cycle Mining Co. v. Christmas Gold Mining Co. (Colorado), 204 Federal, 939. April 14, 1913.

OIL PIPE LINE COMPANIES—NOT COMMON CARRIERS

The amendment of section 1 of the Interstate Commerce Act, providing that the act shall apply to oil pipe-line companies, and declaring them to be common carriers subject to regulation by the Interstate Commerce Commission, is unconstitutional. The purpose and effect of the amendment as applied to oil pipe-line carriers is to impose upon companies which have been doing a strictly private business, the duties of a common carrier and compel them to devote their property to public use without their consent. It is void as depriving them of property without due process of law within the meaning of the Constitution.

Prarie Oil & Gas Co. v. United States (Commerce court), 204 Federal, 798. March 11, 1913.

EXTRALATERAL RIGHTS—VEIN CUT OBLIQUELY BY FAULT

Where a mineral vein has been cut off by a great and well defined fault, and the end edge of the vein along the fault is left in such a position that if the fault were eroded or washed away the edge of the vein would stand out as an overhanging cliff with both a dip and a declination in line with the strike of the vein of from 30 to 45°, such faulted edge of the vein is not a part of its top or apex and no extralateral right can be predicated thereon. Where the discovery vein of a claim crosses both end lines, those end lines are end lines for all secondary veins in the claim regardless of the course of their apices, and bound the extralateral planes of the secondary veins. If such secondary veins cross one side line the locator cannot acquire any extralateral rights thereon beyond the point where they are intersected by the end-line plane of the claim. The burden is always on the claimant of an extralateral right to prove the apex on which it is based. Top or apex of a vein within the meaning of the mining laws, refers to the highest point in the vein. It must be the top of the vein proper rather than a spur, and must be a point from which the vein had a dip as well as a strike.

Stewart Mining Co. v. Ontario Mining Co. (Idaho), 132 Pacific, 757. May 3, 1913.

Recent Publications

MINERAL INDUSTRY OF TASMANIA. Quarterly report compiled by W. H. Wallace, secretary for mines. P. 27. Hobart, 1913. This publication contains details of metal production in this state, and progress of operations.

NATIONAL MINE-RESCUE AND FIRST-AID CONFERENCE. By Herbert M. Wilson. Bulletin 62. P. 74. Index. Bureau of Mines, Washington, 1913. This is an account of the conference held at Pittsburgh, on September 23-26, 1912.

RESOURCES OF TENNESSEE. Published by the State Geological Survey. P. 62. Ill. Nashville, July 1913. This is published in January, April, July, and October, and describes conservation and development of the state. This number contains, among other matter, details of the white rock phosphates of Decatur county.

THE DISTRICT OF UNGAVA, QUEBEC. Compiled from various reports by Theo. C. Denis, superintendent of mines. P. 160. Ill., maps, index. Quebec, 1913. This district was recently added to the province of Quebec, under the name of the Territory of New Quebec. The Indians, *fauna and flora*, geology, and minerals are described.

SLUDGE ABATEMENT. Report of the Board for 1912. P. 22. Plates 29. Government Printer, Melbourne, Victoria, 1913. This publication gives details of the regulation of milling and dredging in this state, so as to prevent the silting of streams and injury to lands by tailing and debris from such operations. Attention was directed to the development and improvement of appliances for resoiling and otherwise restoring the surface of dredged ground to a useful condition for agricultural, horticultural, and pastoral purposes. There has been little trouble in getting those interested to conform to the regulations.

United States Geological Survey. Advance chapters from 'Mineral Resources of the United States, 1912.' Washington, 1913:

PRODUCTION OF ASBESTOS. By J. S. Diller. P. 13.

THE GYPSUM INDUSTRY. By Ralph W. Stone. P. 15.

PRODUCTION OF ANTIMONY, ARSENIC, BISMUTH, AND SELENIUM. By Frank L. Hess. P. 13.

MINING IN QUEENSLAND IN 1912. Annual report of the Department of Mines. Compiled by the secretary, J. George Appel, from the reports of wardens, inspectors of mines, geologists, and others. P. 211. Ill., maps, tables. This report was reviewed in the *Mining and Scientific Press* of May 31, 1913.

ALASKA. OUR FRONTIER WONDERLAND. Published by the Alaska Bureau of the Seattle Chamber of Commerce. P. 93. Ill., map, index. Seattle, May 1913. This is a well compiled booklet, dealing in an interesting manner with every phase of life and industry in a territory covering 586,400 square miles. The population is approximately 70,000, decreasing during the winter months, when many return 'outside'. Imports and exports during 1912 totaled \$72,741,060, the latter including gold, silver, and copper \$21,940,000, fish and furs, \$18,120,133, and miscellaneous, \$394,046. The possibilities of the country are great in metal mining, coal, agriculture, and for tourists, more especially if the United States government constructs the railroads now under consideration at Washington.

THE WEBSTER MFG. CO. Tiffin, Ohio, reports a change in management whereby F. S. Shaw, formerly of Chicago, becomes president; E. P. McPherson, vice-president; A. T. Perkins, who has been with the Company for twenty-five years, general manager; L. H. Webster, identified with the Company for twenty-one years, secretary. The affairs of the Company are now in the hands of men of proved ability, and each department will be brought up to the highest efficiency. Minor changes will be made in the organization as occasion demands. The engineering and manufacturing departments will be strengthened and the reputation of 'Webster products' will be maintained and the Company keep its place as a leader in the manufacture of elevating, conveying, and transmission machinery.

Drilling in Mid-Air

By C. M. HANSEN

At the mines of the Bullwhacker Copper Co. at Butte, Montana, a great deal of glory-hole mining has to be done which would be extremely difficult if a piston drill were employed. Much of the drilling is done in mid-air in places that are almost inaccessible, and often where there is no opportunity for a foothold. However, by means of a jackhammer drill, the miner is able to make good progress with comparatively little difficulty. The dangerous nature of work of this sort is evidenced by the fact that it is 75 ft. from the operator to the bottom of the cut, where the ore which is broken is loaded into the cars and hoisted on an incline to the surface. A low-grade copper ore, averag-

DRILLING AT THE BULLWHACKER PROPERTY.

ing about 4% copper, is mined, the vein averaging about 125 ft. in width at the place where the photograph was taken.

The jackhammer is fitted with an automatic steel-rotating mechanism, so that the miner simply has to apply the tool to the spot to be drilled, open the throttle, and the jackhammer does the rest. In many cases the operator works sitting on a wooden seat in a rope-sling let down over the side of the cliff. The accompanying illustration shows the method of drilling a particularly difficult hole, where a ladder had to be pressed into service. Here the operator has one foot on the ladder and is braced against it. There was just sufficient footing for the left foot on a projection of the rock. A tripod drill would be out of the question for work of this sort, and even an ordinary hand hammer-drill would be extremely troublesome to operate on account of the difficulty of rotating it in such cramped quarters.

Great speed is made in drilling the rock, the jackhammer drilling about 6 ft. every 6 minutes, operating with compressed air. Of course, this record is high, but the rock,

oxidized granite, is not hard. Three-foot starters are used, followed with 6-ft. steel, the holes being drilled to take 1¼-in. powder. A simple steel holder attached to the front head is found to be of material aid in withdrawing the steel from the hole. In addition, it enables the operator to lower and raise the steel in the hole, churning up the cuttings and preventing the steel from sticking or binding. The jackhammer is fitted with a special hole-cleaning device by means of which the operator can at will send a jet of air through the hollow steel to the bottom of the hole, thus keeping the drill-hole clear of cuttings, dirt, etc., without removing the steel. I recently witnessed an interesting performance of this jackhammer drill at the Bullwhacker mine. Drilling was started about 8 o'clock, using only one machine, and by 10 o'clock the same morning fifteen 6-ft. holes had been put in. After these were fired, the shovelers were kept busy until noon of the following day getting the broken rock out of the way. During the month of April 1913 enough ore was mined at the Bullwhacker mine, using one jackhammer drill, to make shipments of 64 cars, averaging about 50,000 lb. each, to the smelters near Butte. The jackhammer drill is one of the products of the Ingersoll-Rand Company.

A Modern Plant for Building Pumps

To take care of the ever increasing demand for its product, the A. S. Cameron Steam Pump Works recently erected a new shop, at Phillipsburg, New Jersey, which is typical of modern practice, in shop construction. Many novel features are to be found in this plant. The Cameron works have grown from a small one-room shop, started in 1860, at the corner of 22nd street and 2nd avenue, in the City of New York, embracing approximately 400 sq. ft. of floor space, to its present extensive modern quarters, giving employment to many men in different departments, and providing for future growth and development.

It is interesting to note the growth attendant upon the manufacture of a product greatly limited in its early scope, to one that is now found as an accessory in various fields. This product has earned a world-wide reputation for quality and efficiency, and it is obvious that true merit alone could be responsible for such growth, both in plant, and the recognition accorded the product as a standard line of pumps, for mining, contracting, boiler plant, and general industrial purposes.

The Phillipsburg plant consists of one main building, 100 ft. wide by 600 ft. long, and a number of auxiliary buildings. The main building is of the central bay type, and is 50 ft. wide at this point, while the wings are each 25 ft. wide. The main bay is traversed by a 10-ton electric crane, taking current from a side trolley. In addition to this large crane, there are a number of small 3-ton traveling cranes, equipped with electrically operated hoists, operating in the wings. The moving question in this plant is a comparatively simple and easy one, due to the splendid provision made, and hand trucks are but very little required. The building itself is of structural steel, brick, and concrete, and is particularly well lighted.—*Compressed Air Magazine*.

Catalogues Received

A. LESCHEN & SONS ROPE CO., St. Louis, Mo. July issue of 'Leschen's Hercules.' 16 pages. Illustrated. 8 by 10 inches.

IT begins to appear that Congress has slipped up on its proposal to tax bananas.

ESTIMATES give the cost of the Balkan war to date at \$1,250,000,000, which seems rather a high price to pay for a slight alteration in the map of Europe.

AN interesting side-light on the testimony of Mr. Daniel Guggenheim in the *Ross v. Burrage* suit in Boston is the bringing out of the fact that it was at first hoped that the Bradley process would prove applicable to the ore at Chuquicamata. Having been supplanted at Chino by ordinary milling, and in Chile and at Anaconda by other wet methods, the devisers of the Bradley process feel that they have come to the time 'when a feller needs a friend.'

IF the insurance rates set by Lloyd's underwriters are to be taken as a standard for judging the security of Mexican investments, the rate of five guineas per cent for six months does not augur well for the future. Eighteen months ago the rate was less than half of what it is at present. This rate, however, was of but short life and soon rose to five guineas per cent for twelve months. At the present but few risks are being accepted, and these only in the undisturbed parts of the country.

ZINC smelting will be the subject of a thorough investigation by the Canadian federal department of mines, according to the plan of Mr. Eugene Haanel, director of this department. This work was started at Nelson, B. C., some time ago, but, like "the best laid plans of mice and man," has not been completed. The lead and zinc industries are to receive special attention under the new program, which includes a recommendation for the erection of an experimental metallurgical plant in connection with the ore-dressing equipment at Ottawa.

THE appointment of Col. George W. Goethals as honorary president of the International Engineering Congress, to be held in San Francisco in September 1915, is an honor well bestowed. As chairman of the Isthmian Canal Commission and chief engineer of the Panama canal, Col. Goethals' name has become so closely associated with this gigantic undertaking that any reference to the greatness of this engineering work is almost synonymous with his name. It is also gratifying to know that Col. Goethals will preside in person over the general sessions of this congress.

THE first International Exposition of Safety and Sanitation will be held in New York City, December 11 to 20, 1913. This will mark the first step toward making a representative exposition of the progress which is being made toward the prevention of accidents. Statistics which have been compiled in the United States show that there are annually killed 40,000 workmen, 2,000,000 injured, and 3,000,000 are ill for reasons which could be prevented by proper sanitary regulation of industrial communities. As mining is generally conceded the most hazardous of the industries from the standpoint of accidents, as well as finance, it is to be hoped that something tangible may result for the good of the industry from the efforts of the exposition.

THE 'lay of the cards' is just as important in the industrial world as it is in bridge whist. A valued correspondent suggests that some should be credited with skillful strategy in the copper world, in that certain directors of the Chicago, Milwaukee & St. Paul railway who are also interested in Montana hydro-electric enterprises, are doubtless therefore easier to convince of the advantages of electrifying the railway system. Similarly, directors who are interested in copper mines may be assumed to be more quick to see the advantages of copper in steel rails. The modern muck-raker would probably find cause for ululation in such relations, but as a matter of fact the moves suggested are based upon sound technology, and the relations which facilitate their adoption are cause for congratulation.

COBALT is becoming deservedly famous for the results attained in metallurgical research, and these bid fair to be as high grade as is the ore. In Mr. Alfred James' annual review last January we published an account of the process developed at the Nipissing high-grade mill, by Mr. Charles Butters and his staff. Fuller details were given in *The Mining Magazine* for June 1912. Aluminum as a precipitating agent was announced in the report of the Nipissing company as reviewed in our columns May 17, 1913. We present this week a general summary of milling conditions at the various Cobalt mills as prepared by Mr. Fraser Reid, the capable mill superintendent at the Coniagas property. It will be noted that a further advance in metallurgy is chronicled in the desulphurizing process developed by Mr. A. J. Denny at the Nipissing low-grade mill. While not permitted at this time to give details, we may state that an advance of first importance in hydrometallurgy has indeed been made and that Mr. Denny's discovery is likely to prove useful in a large number of widely scattered districts. Cobalt is producing much silver, but it is also developing engineers and metallurgists of high caliber and they are adding materially to the fund of technical knowledge.

AMONG the most despicable forms of character assassination practised by journals of a saffron hue is the use of forms of statements so easily misunderstood as to be tantamount to a lie. An instance of this occurs in the *Boston Journal's* report of the suit now in progress between Messrs. Louis

Ross and A. C. Burrage. A two-column portrait of Mr. Daniel Guggenheim, who was a witness, is surmounted by the legend, in letters an inch high, "Drinks on the Witness Stand." The curious one who read the smaller type below learned that Mr. Guggenheim drank some milk mixed with vichy, as a cure for indigestion, but the reader of the headline passed on with the vague impression that Mr. Guggenheim's appetite for highballs and cocktails was so overpowering as to make it necessary to serve them to him on the witness stand. The incident is typical of the sort of treatment accorded any man in the public eye, and it was doubtless by just such methods that the impression was spread broadcast that Mr. Roosevelt drank to excess. The most deplorable feature of the situation is that journals that employ such methods do not suffer sufficiently in public esteem to be deterred. When such methods are reflected in a loss of patronage by self-respecting people, they will cease to be employed.

PERHAPS the most marked characteristic of American political life is the sudden changes which occur in the popular estimate of public characters. The most striking instance of this was in the case of Admiral George Dewey, who in a few months shrank from a national hero to a figure of so little import that few people would be able to state with absolute certainty whether or not he is still living. A more recent example of the same sort is Mr. William Jennings Bryan, who emerged from the Baltimore convention of a year ago the dominant figure in the Democratic party, perhaps even in the whole field of American politics. Immediately upon his elevation to the post of Secretary of State his prestige began to wane. Grape-juice dinners and other personal peculiarities became the subject of that type of ridicule which is exceedingly corrosive to public prestige, and, rightly or wrongly, the people have ascribed to Mr. Bryan the responsibility for the appointment of second-rate novelists, and other equally experienced diplomats, to foreign ambassadorships and the pursuing of a foreign policy of delay and indecision. The announcement that he was about to spend six weeks upon the platform as a paid lecturer has now all but deflated the bubble of reputation. The rest of crowned heads is proverbially insecure, but the course of an American political career is frequently like that of a roller-coaster; a rapid alternation of exhilarating upward sweeps and sudden descents that ends upon the prosaic level upon which it began. The recent appointment of Gov. John Lind as ambassador to Mexico gives rise to the question of the advisability of changing horses in mid-stream.

H EED may well be paid by the striking miners of the Lake Superior district to the lesson of the Paterson strike, where the operators returned to work on July 25 after 21 weeks of idleness with no advantage gained, and \$5,300,000 in wages lost. Miners whose essential aim is to do a fair day's work for a fair day's wage may profit greatly by thoughtful consideration whether the cost to them of the strike is not too high a price to pay for an attempt to secure recognition of a discredited organization.

In so far as this strike, or any other, is an attempt by honest workmen to secure just recompense and proper working conditions, we are in sympathy with its object, though as a means to an end it has much in common with the burning of a barn in order to rid it of rats. Men are fallible, whether they be owners or workmen, and what the workman believes to be a fair return for his labor may be erroneous. A clear recognition of the viewpoint of the other side would avert most strikes and a fraction of the cost to operators and operatives of a single strike, if expended upon the maintenance of a commission for the impartial study of the industrial situation in each important industry or district would produce better results than are now attained by the present illogical system of strikes and lock-outs. We favor no class or group; a wagon moves ahead only when both horses pull on the whiffletree, and human progress results when all groups progress at their due rate. Capital can indefinitely profit through undue advantage over labor, but labor cannot indefinitely profit at the advantage of capital, for if it does, it destroys that upon which it exists. Not long ago a strike in New York state for higher wages and shorter hours resulted in the abandonment of the plant; the company which owned it finding it impossible to operate at a profit and preferring to divert its capital into more favorable fields of work. The miners are not more desirous than we are that they shall receive fair treatment, but we also wish to point out that unless the demands of the miners in Lake Superior and on the Rand are kept within just bounds there will inevitably result such a decline of the mining industry in those two districts that many of the men now employed will no longer find work to do.

The Geological Congress at Sudbury

The visit of the members of the International Geological Congress to Sudbury, July 24 to 26, was made the occasion for many exchanges of courtesy, the renewal of old friendships, and the forming of new ones. Naturally the members of the excursion were especially interested in the stratigraphical geology and the mode of occurrence of the wonderful bodies of nickel ore that now furnish 90 per cent of the world's supply and which at the same time afford a type example of one of the most interesting modes of ore genesis. Under the active leadership of Mr. A. P. Coleman, whose classic studies of the great norite sill are well known, all parts of the field were visited and typical phases of all the rocks were examined. It will be remembered that, according to the theory developed by Mr. Coleman, the nickel-copper ores represent magmatic segregations at the base of an intrusive sill of norite, whose upper portion has, under the same influence, become a micro-pegmatite. The orebodies occur in embayments representing depressions in the underlying beds or pitching troughs, and in 'off-sets' or projections from the main mass of the magma. They contain 4 to 6 per cent of combined copper and nickel in great masses of pyrrhotite. The ores are worked by open-pit and underground methods, hand sorted, and smelted. Wet concen-

tration is unnecessary, and the final product of the district is a high-grade matte, which is shipped to England and the United States for refining.

The interesting feature of a visit to the nickel region just at present is the widespread evidence of the rapidly growing demand for the metal and the evident prosperity of the industry. New mines, new plants, active prospecting, and active construction are to be seen on every side. The Canadian Copper Company, the largest and the pioneer concern, has now a daily output of 2200 tons. Within ten years it is expected that 5000 tons per day will be sent to the furnaces, and as rapidly as possible the output will be increased to 10,000 tons. To supply this amount of ore, extensions of the ore-shoots are being rapidly outlined by diamond-drilling, and extensive changes are being made in underground work. How successful the engineers are in tracing the ore-shoots down the troughs, is suggested by the fact that in the range worked by the No. 3 and adjacent mines, it is now estimated that 50,000,000 tons of ore is known above 1400 feet in depth. There are many interesting phases of the work of this concern, not forgetting the successful firing of reverberatories by means of coal dust; but other mines and plants demand a word or two.

The Mond Nickel Company, Limited, of which Mr. C. V. Corless is manager, is also actively engaged in expanding operations. Drills are at work, a new shaft is being sunk at Froud, and a new and excellently designed smelter has just been put in operation. At present about 500 tons per day is being smelted, but the output is to be doubled by fall. The New Canadian Nickel Corporation is rapidly getting into shape for production. Drilling at the Murray mine has outlined the ore-shoot and proved 8,000,000 tons of ore with a probable 2,000,000 additional. There has been much speculation about the plans of this Company and no authoritative announcement has been made, but it is expected that a refinery as well as a smelter will be built. The great growth of the automobile industry has created a demand for nickel steel that, supplementing the older use in the making of armor plate and that consumed in manufacture of monel metal, affords room for much expansion in the nickel industry. The Pennsylvania station in New York City and the Chicago & Northwestern in Chicago are roofed with monel metal, but with the present active demand for nickel itself there is no incentive to push into this promising field.

The geologists spent an interesting and instructive day at Moose Mountain, where a beginning has been made in marketing the 140,000,000 tons of magnetite that is there available to supplement the hematites of the Lake Superior region. They were also guests at a most enjoyable banquet tendered by the Sudbury Board of Trade, where after a menu that extended from a gossan of lettuce to the "Miners' last luncheon" (angel cake) there were unique features. Sunday the party left for Cobalt and Poreupine well pleased with the beginning of their visit to the 'New Ontario' that is to mean so much in the industrial life of North America.

Milling at Cobalt

By FRASER REID

*In the first three years of the life of Cobalt, there was practically no attempt made to recover the silver locked up in the low-grade ore. A large percentage of the ore was sacked underground and the balance hoisted to the surface and washed, the high-grade being hand-sorted and the low-grade going to the dump. Later, sorting houses were operated. Here the ore passed over a grizzly, the resultant fine material, averaging 125 oz., being shipped direct to the smelter. The oversize passed on to a bumping table, where the first-class ore of from 2000 to 4000 oz., and second-class ore averaging around 400 oz. per ton, were sorted out by hand, and the discards, with a value of from 15 to 30 oz., went to the low-grade dump. It was this rapidly accumulating low-grade product that caused the mine operators considerable concern, and in the fall of 1907 the first concentrator started to operate on this low-grade ore. It was a 5-stamp mill built and operated by the McKinley-

silver, passes on to the regrinding machines for further reduction and concentration.

About 75% of the total ore milled is crushed by stamps, the stamps being in favor owing to the hardness and toughness of the ore and the simplicity and reliability of the stamp as a crushing device. The stamps in some cases are followed by tube-mills. The remaining 25% of the ore is crushed in rock breakers, further reduced by rolls or their equivalent, and finally ground to the desired size by Chilean or Hardinge mills.

Straight Concentration

In straight concentration mills this reground material is classified, the sand being treated on Deister, Wilfley, or James tables, and the slime on James and Deister slimers or Frue vanners. In some mills the tailing from the slime is re-treated on canvas tables when a further recovery at a profit is possible.

COBALT LAKE AND NIPISSING MILLS.

THE NIPISSING PROPERTY.

Darragh Mining Co., and had a capacity of from 12 to 15 tons per day.

Shortly after this the Coniagas mill started with a capacity of 60 tons per day, then followed the Buffalo, Cobalt Central, and others, until today there are 17 mills in operation, with a total capacity of 2000 tons per day and producing silver at the rate of 14,000,000 oz. per year, or nearly 50% of the present production.

Today there are 500 stamps in operation with a dropping weight of 625,000 lb., and rolls to the equivalent of 150 stamps, giving a total dropping weight (if all were stamps) of 800,000 lb. of metal.

Preliminary Treatment

The general practice is to hand-sort the high-grade ore in the mine as closely as possible and send the remainder, containing a portion of vein matter, to the mill. Here it is crushed in breakers, sized, and given a preliminary treatment on jigs and reciprocating tables, and in some cases again sorted by hand. This preliminary treatment usually yields from 30 to 50% of the total silver, and practically means the recovery of vein matter. The wall rock, containing finely disseminated minerals and fine leaf

Up to the latter part of 1912 the cyanide process played a minor part in the recovery of silver, but with new additions to the Dominion Reduction mill and the advent of the Nipissing low-grade mill, this process has now become a more important factor in the production. Owing to their complex nature the Cobalt ores present unusual difficulties in cyanidation, and it is in this field that the greatest advances have been made in the development of new processes. These are of sufficient importance to warrant fuller discussion and will be referred to presently.

Amalgamation

Amalgamation is employed in three mills, the Nipissing and Buffalo high-grade mills treating high-grade ore and concentrate, and the Dominion Reduction treating concentrate only. These mills recover the silver in the form of marketable bullion, thus dispensing with smelting. Amalgamation does not play any part in the recovery from the low-grade ores.

In the treatment of low-grade ores two processes are used: mechanical concentration and cyanidation. Some idea of their relative importance may be gained from the following considerations. There are 13 mills using straight concentration; three use cyanide as an adjunct to concentration, namely, the Buffalo mill cyaniding the slime only; and the Do-

*Read at a reception given by the Cobalt branch of the Canadian Mining Institute to the visiting members of the International Geological Congress on July 28.

minion Reduction, and O'Brien, which regrind the sand tailing from the concentrating process and cyanide the whole. One mill only, the Nipissing low-grade, uses an all-sliming cyanidation process after stamping.

Analysis of Silver Production

An analysis of the total silver production would show approximately the following figures: recovered by sorting underground, about 50%; recovered by preliminary treatment in mills, 20%; recovered by mechanical concentration after stamping, 17%; and recovered by cyanidation, 13%. The ratio of concentration by mechanical concentration averages 37 tons of ore to 1 of concentrate. In an all-sliming and cyanidation process below the stamps, the ratio of concentration ranges from 500 to 1000 tons of ore to 1 ton of bullion, according to the richness of the stamp discharge.

The complex nature of Cobalt ore has developed two processes of importance which are a distinct departure from the general hydrometallurgical treatment of gold and silver ores.

Early in the history of the camp, S. F. Kirkpatrick, professor in Queen's University, undertook some experiments on the cyanidation of Cobalt ore. He found the ore as treated by him fairly amenable to cyanidation, but found that zinc as a precipitant had a great tendency to foul the solution and produce a bullion below the market standard. He finally tried aluminum as a precipitant. This had been discovered and patented by Moldenhauer, who claimed that not only was it a satisfactory precipitant for silver, but that it regenerated the cyanide in chemical combination with silver. Moldenhauer used the aluminum in the form of plates, which soon became coated with aluminum hydroxide and the action was seriously retarded and the process was consequently impracticable. Mr. Kirkpatrick substantiated all the claims of Moldenhauer and made the process commercially successful by using aluminum in the form of dust. This aluminum precipitation process has been very successful, as it leaves the solution unimpaired and gives a marketable bullion.

It is now in use in the O'Brien mill, the Deloro smelter, and in a slightly modified form in the Nipissing mill and the Buffalo high-grade mill.

Desulphurizing Process

The other process referred to is the desulphurizing process as worked out by A. J. Denny, resident metallurgist of the Nipissing mine, and is in operation at the Nipissing low-grade mill. This mill represents the very latest practice in cyaniding, and is a credit to R. B. Watson, general manager for the Company, and his metallurgical staff. The details of this process have not yet been made public and are therefore not available.

It can be said that by this process refractory silver compounds such as sulph-antimonides, which are with great difficulty dissolved by the ordinary cyanide process, are broken up and desulphurized and rendered readily soluble. This process not only increases the extraction but shortens the time of treatment. The importance of this discovery may be realized when it is said that the process is equally ap-

plicable to the cyanidation of refractory gold ores. The process therefore marks a distinct advance in the art of hydrometallurgy and will undoubtedly be generally used in the treatment of refractory gold and silver ores.

In conclusion I might say that I have not attempted to touch on the relative efficiencies of the different mills, as this is a very delicate question and is as complex to the millman as the origin of ore deposits is to the geologist.

The Bullfinch Proprietary Mill

This is a 200-ton plant which has recently been built by the Bullfinch Proprietary on its property in the Yilgarn goldfield of Western Australia. The following details of treatment and equipment are taken from the report of the Company for 1912. The mine ore will be run over a grizzly with 2-in. openings, the undersize falling into a bin holding 200 tons, and the oversize passing to a No. 5 Symons crusher, driven by a 40-hp. motor, which reduces it to about 1½ in. and passes it into the 200-ton bin, where it mixes with the undersize from the grizzly. Two Challenge feeders deliver the ore to a 16-in. belt conveyor, 275 ft. long, which carries the ore to an automatic tripper over the main mill-bin, holding 400 tons. It is fed from this bin by automatic feeders to 15 stamps (1250 lb.) driven by a 50-hp. motor; from there the crushed ore is delivered to a 40-ft. tailing-wheel on reinforced concrete foundation driven by a 25-hp. motor, which elevates it to two conical classifiers having diaphragms and annular launders. The underflow from the classifiers goes to a 4 by 16-ft. tube-mill, 40-hp. motor, and then through an 8-ft. grinding pan to amalgamate the coarse gold, thence returning to the tailing-wheel and classifiers. The overflow from the latter is delivered to two thickeners (Forbes type), 8 by 25-ft., and holding 24,700 gal. each, and then to two 6 by 25-ft. settling-tanks; both thickeners and settlers have bottom discharge vents and annular overflow. The clear solution then flows to the battery feed (return water) tanks. The pulp underflow from thickeners and settlers passes to four agitation vats holding 43 tons each of 1.454 specific gravity pulp. After agitation the pulp is elevated by a Premier pump to three No. 3 Ridgway filters, each having 800 ft. of filtering area. The gold solution from these filters is elevated by three vacuum pumps to the 6 by 14-ft. gold solution tank feeding the clarifier. The residue from the filters is discharged into two mixers, mixed with water, and pumped away by an 8-in. double plunger pump. The solution from the clarifier passes to three zinc boxes and to the sump. The solution from the sump is pumped by a 2-in. Gwynne's centrifugal pump to the wash baths of the filters, the surplus returning to the battery feed tanks.

Pig iron production of Germany during the first half of 1913 amounted to 9,567,666 metric tons, against 8,564,988 in the previous year. There were increases of foundry pig, Thomas iron and steel, and spiegel iron, but a decrease of bessemer and puddled iron.

Agricola: An Appreciation

By F. LYNWOOD GARRISON

It is refreshing and reassuring to find a scholarly gentleman and his wife ready to devote much time and limitless pains to the preparation of a great literary work. This is especially so in view of the fact that after having achieved professional success and reached a period of life when most of us would

fact, the earliest text-book on mining that is worthy of mention. Agricola drew from most of the writers before his day, tainted though they usually were by the fantastic vagaries of the alchemist; moreover, he wrote in an age when men still believed in hobgoblins and gnomes. These primitive superstitions

were particularly strong among the mining communities in the mountainous districts of Europe.

That Agricola should have given some countenance to such beliefs in that superstitious age, while disappointing to us from a man of such breadth and soundness of mind, indicates that he was for all that a human personality, susceptible to the influences of his environment. It is greatly to his credit and shows that he must have been possessed of a cultivated mind to have resisted these influences as much as he did, for on the whole his writings exhibit little taint of mysticism or leaning toward the supernatural. Indeed, he holds the 'divining-rod' up to scorn and explains the simple manipulation of this ancient humbug, whose efficacy is even today believed in by persons one would suppose knew better.

The period in which Agricola lived and wrote was a notable one; it was the time of the great spiritual awakening which ushered in modern thought and tolerance. The Reformation was at hand, and men's minds were filled with religious disputations resulting in wars and persecutions which had a most profound effect upon the development and history of our own country. Indeed, in many respects the sixteenth century was the most notable in modern history. In 1609 Spain suddenly evacuated the Dutch Netherlands baffled and beaten, although she was then the richest and most powerful nation in the world, having taken from America up to that time, a treasure estimated by Fiske equal to five billion dollars of our present

SIEVING AND WASHING THE ORE.

fain relax its strain, these good people saw fit to burden themselves with this tremendous undertaking in order to give to their less fortunate and less erudite brethren this justly famous book in scholarly English. "*Scire tuum nihil est, nisi te scire hoc sciat aller.*"

A Great Technical Work

Agricola's 'De Re Metallica' is not only for its day, a preëminently great technical work, but is in

money. This huge sum was used to maintain the gibbet for political reformers and the stake for heretics. The Protestants in northern Europe must indeed have been a sturdy lot to have successfully resisted and finally defeated Spain. At that time the population of England, which formed the backbone of the Reformation, was not over five millions, or somewhat less than that of Pennsylvania today.

Agricola, or to give him his true name, George Bauer, lived in the centre of this religious turmoil.

for Saxony was violently Protestant. And it speaks well for his strength of character and manliness, that he clung to the old faith amidst such inimical surroundings. It is said that he died a good Papist at Chemnitz, March 25, 1555, and the zeal with which he opposed the Protestant in his latter days rendered him so odious to the Lutherans that they let him lie five days unburied. Finally they brought his body from Chemnitz to Zeitz, where it was interred in the principal church. In earlier years Agricola appears to have been influenced by the Reformation, as any thinking man must have been, for he wrote the following verses concerning indulgences, which were posted in the streets of Zwickau. Translated freely from the Latin they read thus:

"If without gold salvation can't be bought,
How cursed the wretch who is not worth a groat;
But if Christ's death has purchased for us peace,
Rejoice ye poor and bid your miseries cease."

Agricola was called by Cuvier, the first mineralogist, using the term in an old sense as one who knew metalliferous minerals, their extraction and refining, who appeared after the renaissance of the sciences in Europe.

In reading this book one is forcibly impressed with the fact that Agricola was not only learned but an accurate man, who faithfully describes mining and metallurgical operations as he saw them. That the science has advanced little in the fundamental principles underlying these arts in the three hundred and fifty years since he wrote, must be admitted. Especially is this the case in assaying, which may be regarded as the father of modern analytical chemistry.

Mining Laws

Agricola's observations upon the mining laws of his time are of great interest, for it is evident that there has been but little change since that time. The German mining law as a whole, at any rate in the sixteenth century, may be said to have been the product of antagonism, a compromise growing out of the struggle to maintain the right of free mining against the prerogatives of royalty. One can also learn from him that the archaic apex or extralateral law, did not originate, as some have thought, in Gilpin county, Colorado, but in old Saxony, passing thence to Derbyshire, England, and then to the United States, either from Derbyshire or, as the Hoovers believe, directly from Saxony.

One is impressed by the thoroughness with which all mining operations were regulated by the local authorities in Agricola's time. Mining then seems to have been a public privilege, not a private right. The inspections were frequent, thorough, and severe. They even fixed the wages of the miners, which were raised or lowered according as the rock was soft or hard. If a foreman made complaint of any particular miner as being lazy or negligent, the Bergmeister made deductions from his pay. The Bergmeister, the manager, and two jurors in agreement with the owners, regulated the pay of all the miners; the men themselves do not appear to have had anything to say in the matter. If the workmen were reported by the foreman for negli-

gence, the Bergmeister or even the foreman himself, jointly with the manager, dismissed them, or deprived them of part of their pay, and if caught in a fraudulent or dishonest practice were thrown into prison. 'High-grading' was an art yet to be learned and awaited opportunity to develop under more democratic conditions. The German miner of the sixteenth century, like his agricultural brother, was unlearned, simple, and unspoiled. The follies of a socialistic democracy were unknown to him, and he

HOISTING BY WATER-POWER.

was content to live and die in the sphere in which he had been born. One is often told today that illiteracy breeds discontent, whereas the truth is probably to the contrary. The most illiterate people in Europe are the Russian peasants, yet it is a fact they are the least discontented, the most hospitable and kindly in the world. It cannot be proved that the enlightenment of the laboring classes has been productive of contentment, which is in fact the only real essence of happiness, nor may it be successfully demonstrated that the modern facilities for travel and getting about quickly have either made more happiness or increased the leisure time.

Technical Advancement

In so-called social development, great strides have been made since Agricola's time, but how little we have actually advanced in practical matters appertaining to mining, the reader of this book may judge for himself. The question is, is not science rapidly

reaching a dead-level of educated mediocrity. Where today are the Shakespeares, Galileos, and Luthers? Agricola may, it is true, have been surrounded by an illiterate peasantry, but he was also a contemporary with some of the greatest minds in history. And, indeed, if we are not greatly mistaken, he was something of a great man himself.

Ore Dressing and Smelting

Nearly two-thirds of the work is devoted to assaying, ore dressing, and smelting. Less than the other third covers his observations on actual mining operations, machinery, and ore deposits. The relatively less important part, to which he assigns what has come of late years to be believed the most important part of mining, may be explained by the fact that Agricola was a physician, a man of letters living in small mining communities. As such he was probably anxious to avoid the dangers and discomforts so many people unaccustomed to mines experience in going underground. Probably he spent little time there, as compared with the months and even years he devoted to the study of the operations necessary to extract the metal from the ore. Anyone familiar with mining may readily understand this feeling, and it is a valid criticism, I think, of some of our modern mining engineers, that they give too little attention to underground work and the study of geologic phenomena. Millmen, assayers, cyanide-specialists, and smelter-men we have a-plenty, but the engineer who is a good miner and economic geologist, is comparatively uncommon, at least such has been my experience.

It is to Agricola's credit that he does not disfigure his text with the senseless speculation so popular with the semi-learned and charlatan before and since his time. He tells many of the homely rules and facts which experience had taught the miner of those days in his limited environment of central Europe. It is highly improbable the Germans of the sixteenth century knew much of mining conditions outside their own country, or even local districts. Present day knowledge, it should be remembered, is the result of observation and experience gleaned from all over the world as the result of centuries of mining development.

In connection with Agricola's remarks regarding veins, etc., the Hoovers have added a footnote which is in itself an historical essay on the theories of ore deposition prior to the seventeenth century, and as such is an exceedingly valuable contribution to our literature. It should be carefully read and treasured by all students of economic geology (reprinted in *Mining and Scientific Press*, October 5, 1912).

Vein Formation

Agricola likened underground circulation to that of the blood in the veins of the human body. "Veins in the earth, just like the veins of an animal, have certain veinlets of their own, but in a contrary way. For the larger veins of animals pour blood into the veinlets, while in the earth the humors are usually poured from the veinlets into the larger veins, and rarely flow from the larger into the smaller ones." It should be observed in this connection that Agri-

cola's theories on ore deposition are contained chiefly in an earlier work entitled 'De Ortu et Causis Subterraneorum' (Origin and Causes of Subterranean Things), and that in the 'De Re Metallica' they are merely summarized.

The Hoovers, by footnotes, have incorporated into this translation the gist of Agricola's views as given in his other writings.

In order to clearly understand Agricola's reasoning and point of view, it is well to know something of the geology of the districts in which he lived and worked. Chemnitz, Joachimsthal, Annaberg, Altenberg, and Freiberg are typical mining districts in crystalline or metamorphic rocks, whereas at Mansfeld in the Harz mountains, a locality with which it

STAMP-MILLING.

is easy to see that he was familiar, the rocks are sedimentary (Kupferscheifer) impregnated with copper in certain stratified beds or horizons.

Classification of Fissures

One footnote substantially sets forth Agricola's views upon the origin of ore deposits. He regarded the openings in the earth as resulting from the erosion of subterranean waters. The filling of these openings (canales) is due to circulating waters and juices. He divides the fissure fillings into four classes of material. (1) 'Earth,' which comprises clay, ochre, marl, and 'peculiar earths.' These 'earths' had their origin from the rocks and were transported and deposited by the circulating waters. (2) The 'solidified juices' comprise salt, soda, vitriol, bitumen, etc., and were substances he conceived to be soluble in and deposited from water. (3) 'Stones' comprised precious, semi-precious, and unusual stones, as distinguished from country rock. The origin of these he attributed in part to the transportation of fragments of rock, but in the main to deposits from mineral lapidifying juices. (4) 'Metals', comprising the seven traditional metals and the compounds, comprised the metallic minerals, both being deposited from juices, the compounds being due to a mixture of juices. Each substance had its own

particular juice, which became solidified by evaporation (such as salt), or by lowering of temperature below the fusing point. The origin of these juices was two-fold, some being generated by the solution of their own particular substance; but in the main their origin was due to the combination of 'dry things,' such as earth with water, the mixture being heated and the resultant metals depended upon the proportion of earth and water.

Ore Deposits

In a general way Agricola divides metal deposits into three classes (a) *vena profunda*, fissure veins; (b) *vena dilatata*, bedded deposits; (c) *vena cumulata*, and impregnation, a replacement or a stock-work. Two great fundamental principles of ore deposition were established by Agricola, namely, that ore channels were of origin subsequent to their containing rocks, and the ores were deposited from

tions regarding directions of strike and dip were quite popular before the present theories regarding ore deposition began to take shape, but it is certain they should not now be regarded with any degree of favor. It is difficult, even in these present enlightened days, to make people understand that to have ore deposits one must not only have solutions or vapors that convey the metals, but also convenient receptacles for their deposition together with conditions which would bring about precipitation, or at least a replacement of some of the minerals in the associated rocks. Agricola clearly saw that the existence of veins were predicated upon the presence of voids, and that the ore in the veins was simply a filling of later origin than the voids. These views are today as fundamentally sound as they were three hundred years ago, although of course they are much modified by the present vastly more comprehensive and thorough knowledge of the subject. That Agri-

FISSURE VEINS.

THIN AND THICK VEINS.

solutions circulating in these openings. These dicta, as the Hoovers state, represent a much greater step from what had gone before than almost any single observation since. He was the first to grasp these concepts and apply them in his deductive reasoning.

Strike and Dip

In Agricola's time, in fact down to my own student days, thirty years ago, much stress was laid upon the direction of the strike and dip of the veins. While it is often true in certain districts that veins have a more or less uniform direction in this respect, it does not follow that any particular veins having, say, a northeast and southwest strike are likely to be richer than those having a northwest and southeast strike, or an east and west or a north and south trend. Such empirical rules may hold good in one or several closely related districts, and be due to regional geological fracturing or some other local peculiarity, but because one finds the richest veins, for example, in Arizona,¹ to have a more or less uniform direction of strike, it does not follow that one has any right to expect similar tendencies to be exhibited by the veins of Alaska or Ontario. These no-

cola apparently did not have much faith in the direction theories regarding veins is evidenced by what he says on the subject. He intimates that the actual experience of miners in this respect does not always accord with their opinions, and he cites a case at Annaberg where a vein striking north and south and "whose head rose toward the west" was no less rich than the other veins "whose heads rise toward the east."

Importance of Geology

It has been assumed for years that Werner was the father of our modern theories of ore deposition. Although Werner had the advantage of writing two hundred and forty years later (1791), Agricola's observations and deductions are sounder and more in harmony with modern views. In fact, it seems that the theories regarding ore deposition not only failed to improve in the long interval between Agricola's time and the beginning of the nineteenth century, but they actually retrograded, and the student's mind was filled with rubbish which would have been repudiated by Agricola. It seems to me that, even today, too little emphasis is laid upon the geologic side of a mining engineer's training; its vital importance is perhaps more fully recognized than thirty years ago, and although it is as essential to a mining engineer as anatomy to a physician, many schools fail to appreciate its fundamental

¹I do not mean to suggest that such a rule will hold good for Arizona or any part thereof. Some uniformity of this kind may be found in one or more closely related districts, but it should not be accepted as covering any large area, such as a whole state.

character. It will be found, I believe, if the trouble was taken to ascertain, that our most efficient mining engineers of today are also excellent geologists. They may not be able to identify a fossil, or give the exact technical name of any igneous rock at first glance, but it will be evident they are possessed with a thorough understanding of theoretical dynamic geology and chemical phenomena as affecting ore deposition and the formation of alluvial deposits.

By efficient, I do not mean necessarily success in money getting. That is doubtless the easiest and commonest standard for measuring efficiency, but we all know it is not always the correct one. A mind absorbed with technical work has no room for the schemes or the keen watch for opportunity necessary in money getting. Hence, your efficient engineer is often singularly thoughtless of himself in such matters.

Mining and Milling Machinery

The mechanical apparatus used for mining and ore preparation in Agricola's time exhibits some things commonly supposed to be of modern origin. Thus are found illustrations showing the link belt fully developed and in practical use. A careful study of the text and illustrations in this book indicate that the mechanical arts in principle, were well advanced in the sixteenth century, and that while these fundamentals have been enormously elaborated, the original stock of ideas has not been greatly added to. Steam has largely replaced animal force and water-wheels for power generation; explosives now shatter the rock which once yielded only to fire and manual labor. The expansive power of steam was known to the ancients, but that compounds could be produced whose elements were in such a state of delicate equilibrium that heat or shock would change them instantly to gases of a more stable character with the production of power caused by the explosive violence of the change, was something absolutely undreamed of before the introduction of gunpowder into Europe. In other words, chemistry is a distinctly modern science, whereas metallurgy, including assaying as an empiric art, has its roots deep down to the beginning of human history.

It is not my purpose to detail or summarize the various mechanical and metallurgical appliances and methods described by Agricola. This has been excellently done in other reviews of this book; moreover, it is rather tiresome reading except such details as may be of special interest to the reader.

The historical and metallurgical footnotes of the translation are an invaluable addition to the book. They have evidently been prepared with the greatest care and painstaking industry, in fact, each is a historical and technical essay of the particular metal or subject under discussion. The last, or twelfth book, of this great work, Agricola devotes to the preparation of salt by evaporation from natural saline solutions; to the production of nitre, alum, bitumen, etc., and finally a detailed description of the manufacture of glass. It is probably doubtful if Agricola was personally acquainted with many of the processes and much of the apparatus he describes, but he evidently drew from reliable sources for his details.

Perhaps the most interesting feature of the whole work is the illustrations, which are elaborate as to details, quaint, and accurate. Anyone who enjoys looking at 'pictures,' and I confess to this childish weakness, may profitably spend hours studying these old woodcuts. To me, the chief and virile interest of the subject lies in Agricola's personality and the sidelights his writings throw upon his times. They suggest philosophical reflection and the introspection of our own life and times; such musings are perhaps of small interest save to the one who makes them, and modern conventions do not ordinarily invite such confidences.

How much better off are we than the Saxon miner of Agricola's day? Are we happier, more contented and comfortable? Is this fierce modern scramble for wealth and education improving our lives, or homes, and our country? Is this intense effort to exploit and develop the latent resources of the earth justifiable, or is it not rather a consequent phase of social discontent and a fancied political freedom? Are our homes better, more wholesome than the simpler ones of our parents and grandparents? This is the crux of the whole problem, for as the home is, so will be the nation. Will the hand that rocks the cradle, and was once said to rule the world, be better for having a finger on the ballot box? These are grave questions which sooner or later every thinking man and woman must ask him or herself, and the fate of our own great and beloved country will rest upon the correctness with which they are answered. They cannot be solved by the agitator, the newspaper, or the militant suffragette, but must come from deep down in the soul of every man and woman in this great, restless, and often unthinking nation.

Value of the Work

But I am wandering away from my ancient friend Agricola and his book—I have but a few more words to add. Every mining engineer who is interested in his profession as other than simply a means of livelihood, may read this work with profit and interest. I do not wish to advertise, for it needs it not in a commercial sense. I do, however, desire to remind the public that this is a real gift, a great labor of love freely bestowed by an eminent mining engineer and his wife, who, I wot not, have builded better than they knew in this unselfish evidence of devotion to an honorable profession, comparatively little known, and I sometimes fear not fully appreciated by those who would fain sail the stormy seas of mining speculation. The promoter's object is to make money for himself, out of the mines if he is honest, or out of the public if he be unscrupulous. It should be the business of a mining engineer to prevent unwise mining investments or ventures and to make of it a commercial affair, the profit coming from the mine itself. The engineer is, therefore, a check on the promoter, and the investor who listens to the latter without the advice of the former is in the end likely to play the fool. These two classes of men are indispensable to the industry, some men may be both engineer and promoter, but as a rule such a plan spoils the engineer and makes an indifferently different promoter.

Hardinge Mills v. Chilean Mills

By ROBERT FRANKE

*In view of the prominence which the conical mill has attained in the fine-crushing field within the few years since its introduction, the following comparison with its more mature forerunner, the Chilean mill, based on extensive tests, is submitted in the interest of the milling profession.

Hardinge Mill at Miami

Soon after designing the concentrating plant of the Miami Copper Co. in 1909, the Hardinge conical mill made its appearance in the milling forum. Its possibility as a suitable crushing device for the plant was well recognized, but in view of the lack of commercial demonstration, at the time, as to capacity, efficiency for desired product, and the still more uncertain factors of cost of maintenance and power consumption, it was deemed that the immediate adoption of this machine throughout the plant would be a hazardous undertaking. For these reasons it was decided to equip the majority of the immediately required units of the plant with Chilean mills, the fine-crushing proficiencies of which were better known, and one unit with Hardinge mills, to serve as a test plant for the guidance of future installations and replacements. Thereby, after 1½ years operation with both types of mills, a thorough test as to metallurgical efficiency and cost economy has been obtained.

The conical mill used in these tests is the 8-ft. Hardinge pebble-mill, having a cylinder 22 in. long. The cylindrical part of this mill is lined with cast iron liner plates, and the conical extensions with silex bricks bound together by cement. Each liner plate carries a projecting lifter, the function of which is to increase the height of drop of the lifted material. Danish No. 5 pebbles, obtained from the coast deposits of Denmark, are used for the grinding charge. The Chilean mill used is a fast-running, 3-roller, 6-ft. Saturn mill, with screens of 0.037-in. opening. The feed to these mills is the oversize of Callow screens having 0.029-in. openings, which follow rolls crushing to $\frac{1}{2}$ inch.

Advantages of the Conical Mill

For the ore of this mine, a moderately hard but fissile schist, impregnated with finely disseminated granular chalcocite, the conical mill has proved itself superior, metallurgically and economically, as a fine-grinding machine. This superiority is attained by a combination of commendable characteristics, namely, smoothness and steadiness of operation, delivery of a product enabling better extraction, more economical water consumption, a lower operating and maintenance cost, and a low rate of depreciation.

Steadiness in operation, of paramount importance in plants of such large capacities, is effected in this type of mill by its simplicity in principle and the

*To be presented at the Butte meeting of the American Institute of Mining Engineers, August 1913.

consequent simplicity in construction. Discharge screens, dies, and mullers are eliminated, and in their place more desirable crushing equivalents are substituted. Thus the screen of the Chilean mill is replaced by a perpetual device; the dies by linings which have long life; and the mullers by flint pebbles which are replaceable without interruption to operation.

Delays with these two types of mills in this plant have been found to be as follows:

CHILEAN MILLS		HARDINGE MILLS	
	Per cent.		Per cent.
Screen delays	0.57	Re-lining delays	0.71
Repair delays	1.54	Repair delays	0.58
Total delays	2.11	Total delays	1.29

From the above it is seen that the delays of the Hardinge mill approximate 60% of those of the Chilean mill, and that relining constitutes more than one-half of the total delay. This is mainly due to the fact that when a mill is relined it must be idle about 48 hours, so as to give the cement used for binding time to set. This delay, however, can be materially reduced by means of shell stands, so that a newly relined shell will always be ready to be replaced by an overhead crane when a worn-out shell is to be removed. Allowing 2 hours for this replacement, the delay from this cause will be reduced to about 0.05%. Thus the necessary delays with this mill are reduced to those of repairs to bearings and pinions, lifting out a shell with worn lining and reinstating a new one, and the occasional replacement of feed scoops, which approximate a total delay of about 0.6 per cent.

Labor Charge

Less actual attendance is required by the Harding mill. This makes it possible to reduce the operating cost in plants where the duty of the attendant can be so distributed as to include the supervision of other apparatus. Occasional pebble feed, lubrication, and a lookout for obstructed discharge boxes, are the only services required. By their adoption in this plant the operating labor cost of fine crushing has been reduced about one-half.

For the reduction practised at this plant, the conical mill has proved itself to be a much superior fine-grinding machine. Because of the generally granular character of the chalcocite of this ore, it is the aim to make a product of such size as will liberate a maximum mineral content with as small a production of ultra fines as possible. It has been found that a product which contains a maximum percentage between the sizes of 60 and 200 mesh is best. Below is given a typical screen analysis of feed and product for both types of mills. From this it is seen that the Hardinge mill yields 37% of the desired size of material, or about 50% more than the Chilean mill, and with a smaller production of slime.

Chilean Mill.			Hardinge Mill.		HARDINGE MILL		Cost per ton.
Mesh.	Feed.	Product.	Feed.	Product.	(Tons milled, 450,000.)		
+ 4	13.9	...	12.9	...			\$0.00036
+ 10	47.5	...	47.3	...	Shafts, pinions, and gears		
+ 20	22.9	2.3	26.8	0.2	Lining:		
+ 30	5.2	11.8	5.0	3.2	Liner plates and lifters		\$0.00403
+ 40	0.9	6.7	0.8	4.9	Sillex		0.00300
+ 60	1.0	11.4	0.8	13.8	Cement		0.00050
+ 80	0.5	6.7	0.4	10.4			\$0.00753
+100	0.4	5.4	0.3	8.6	Pebbles (2.51 lb. at \$0.013)		0.03262
+150	0.5	6.3	0.3	8.0	Miscellaneous		0.00012
+200	0.7	7.2	0.5	10.0			
-200 sand	1.2	10.6	0.8	10.0	Total supplies		\$0.04063
-200 slime	5.3	31.6	4.1	30.9	Repair labor		0.00268
					Shop expense		0.00214
					Total maintenance cost		\$0.04545

The Hardinge mill also consumes less power. At this plant, a 150-hp. induction motor operates three 8-ft. Hardinge mills or two 6-ft. Chilean mills, and the power consumption for the above reduction is as given below. The consumption is given on the basis of both crude-ore tonnage and actual feed tonnage, the latter being approximated at 70% of the former.

	Crude-ore tonnage. Hp-hr. per ton.	Actual feed tonnage. Hp-hr. per ton.
Chilean mill	7.5	10.7
Hardinge mill	6.7	9.6

A striking feature brought out by the comparative operation of these mills is the difference in the duty exacted of the cone tanks. The units of the plant operated with Hardinge mills have shown an average reduction of nearly 75% in the solid feed and a 40% reduction in the water feed to these tanks, as compared with the Chilean mill. This is to be attributed to the combined result of the smaller quantity of water fed to the grinding mill and of the smaller production of slime. For plants where the production of extreme fines is not desired, the opportunity is thereby offered of lessened outlay for dewatering equipment.

Cost of Maintenance

The maintenance costs of Chilean and Hardinge mills are shown in the accompanying tables. The cost for each mill is based on crude-ore tonnage, so that the cost per ton of actual feed would be 40% greater than the cost shown, as in the reduction practice of this plant about 70% of the crude-ore tonnage passes through the fine-grinding mills.

The figures presented below cover a wide range of operation, and, going into detail as to maintenance, afford an interesting comparison.

CHILEAN MILL	
(Tons milled, 826,000.)	
Driving mechanism:	Cost per ton.
Shafts, pinions, and gears	\$0.00230
Spindles, muller bushings, etc.	0.00275
Miscellaneous	0.00042
	\$0.00547
Crushing mechanism:	
Dies (12,910 tons per die)	\$0.01079
Tires (7310 tons per tire)	0.00987
Screens (183 tons per screen)	0.00893
Miscellaneous	0.00176
	\$0.03135
Total supplies	\$0.03682
Repair labor	0.00841
Shop expense	0.00543
Total maintenance cost	\$0.05066

From this it is seen that the Hardinge mill, for the practice of this plant, shows a maintenance cost of about 0.5c. per ton less than the Chilean mill. It is to be noted, however, that pebble consumption constitutes 70% of this cost, and the freight on pebbles comprises approximately 50% of their expense in this locality. The item of 'shafts, gears, and pinions' is probably somewhat low, in that these mills have not been operated sufficiently long to obtain a true average. Nevertheless, this part of the cost is small, since these gears have a long life, and, constituting but a small percentage of the total, is inconsequential.

Depreciation

However, the decisive factor of the lower cost of the Hardinge mill is its low rate of depreciation. The life of its shell, if proper care is taken that the lining is not allowed to wear through to it, seems comparatively infinite. Six Chilean mills have shown an efficient life of 825,000 tons, making the rate of depreciation, inclusive of transportation and installation costs, about 3c. per ton. Allowing a life of 10 years for the Hardinge mill, its depreciation cost would be less than 0.5c. per ton.

Summarizing these factors, the net gain in cost by operating with the Hardinge mill, for the practice of this plant, shows as follows:

	Cost per ton, cents.
Operating.	
Labor	0.50
Power, 0.6 kilowatt-hour	0.75
	1.25
Maintenance	0.50
Depreciation	2.50
Saving	4.25

To the above are to be added other advantages, the more conspicuous of which are: greater capacity by reason of lower power consumption and lower delays; superior product enabling a better extraction to be made; smaller water consumption; and for minimum slime practice requires less dewatering equipment.

Furthermore, this mill is not yet out of the experimental stage, and there are possibilities of still better performances. For instance, by lengthening the cylinder of a 6-ft. middling re-crushing mill from 22 to 38 in., it was found that the capacity of the mill was doubled, the power consumption lessened, and the pebble cost decreased to nearly one-half. It would seem, however, that this idea

can be carried too far, for the more the cylinder of this mill is lengthened, the more it tends to approach a tube-mill, and so become a slimer. For re-grinding middling, however, this variation in dimension is a step in the right direction, in that the liberation of occluded mineral necessitates a fine product. Also large percentage variation in the sizes of feed seems to have a considerable influence on the consumption of pebbles. Thus it was found in a test in which all the feed was sized through 2.5 mm., that the pebble consumption was 1.85 lb. per ton of actual feed as against a consumption of 3.60 lb. with the oversize feed shown in the table.

Mechanical Crushing Efficiency

An interesting comparison which, while based on rather ideal assumptions, is so decisive in result as to be given credit, is the mechanical crushing efficiency of these machines determined by the method of calculation discussed by Algernon Del Mar in his article on 'Mechanical Efficiency of Crushing.'[†] These calculations, as shown in the accompanying tables, are based on Rittinger's law that "the work done in crushing is proportional to the reduction in diameter." This assumes that all surfaces exposed give the same unit resistance to crushing, whereas it is to be inferred that there are some surfaces which, by reason of inherent fissility of the

[†]Eng. & Min. Jour., Vol. XCIV, No. 24, p. 1129 (Dec. 14, 1912).

ore, offer a lower unit resistance than surfaces not so favored. However, in view of the large number of surfaces produced, it would seem reasonable to assume that an average unit resistance to crushing will prevail in a not unduly long test. Furthermore, since in these calculations both machines are treated equitably with regard to the practical variations which do not enter into the law, the comparative results can be considered fairly reliable.

Table I shows the crushing efficiency without regard to quality of product made, from which it is seen that the units of reduction performed by the Hardinge mill exceed those of the Chilean mill by from 18 to 23%, depending upon the degree of accuracy attained in the assumptions made in the calculations, and considering 5% as a safe limit. This evaluation proves that the Hardinge mill converts more of the power consumed into reduction of the charge than does the Chilean mill.

Table II shows the comparative crushing efficiency with regard to size of product made. From this it is seen that in amount of work performed on the various sizes of the feed, the Hardinge mill exceeds the Chilean mill in all cases, again showing that this mill converts more of the power taken by it into actual work done. Furthermore, the excess work done is mostly expended on the grades of product desired, thereby proving that this mill more efficiently fulfills the duties assigned. It is here that the cone comes into play. This geometrical device serves the function of adjusting the crushing en-

TABLE I.—MECHANICAL CRUSHING EFFICIENCY, HARDINGE v. CHILEAN MILLS

On basis of law that "the work done in crushing is proportional to the surface exposed in crushing" and therefore "nearly proportional to the reduction in diameter" or "nearly proportional to the reciprocals of the diameters crushed to."

Excess units of work done by Hardinge mill, 10,847.
Excess efficiency, assuming method of calculation correct, 23.45 per cent.
Excess efficiency, assuming 5% as the limit of error, 18.45 per cent.

ergy expended so as to be proportional to the force required to reduce the particles to a given size. This is effected by two principles that are inherent with the operation of the mill. First, through the continual displacement of the larger particles of the charge upon the smaller, there takes place a segregation of the particles in the cone according to size—the larger assuming positions at the greater diameter and the smaller receding toward the smaller end of the cone of the mill; second, through the combined action of this segregation and the diminishing action of centrifugal force toward the apex of the cone, varying intensities of energy are imparted to the pebbles—the larger receiving greater inertia by reason of greater mass and greater lift, and the smaller less and less inertia by reason of the smaller mass and lower lift.

Grinding Zones

There exist within the mill an orderly arrangement of zones of ore particles, each requiring a certain amount of impact to be reduced to a given size, and a series of zones of forces so arranged as to impart impacts that tend to be proportional to the crushing energy required by the ore particles upon which these forces are exerted. For these reasons the production of slime is minimized and the accumulated forces are utilized to best advantage, whereas in the Chilean mill the crushing forces are uniform and disadvantageously expended upon a mixed aggregation of coarse and fine particles.

Thanks are due to J. Parke Channing, consulting engineer and vice-president of the Miami Copper Co., for permission to publish these data. I am also indebted to B. Britton Gottsberger, general manager, for his kindness in placing at my disposal the metallurgical data of these tests.

The Hardinge ball-mill has also been tested in this plant as a substitute for rolls, for intermediate crushing on 1/2-in. material. This mill, however, was soon discarded, since it was found that the desired product could only be obtained at too low a capacity, and the consumption of steel balls was too great to be economical.

Compensation for Accidents

On July 12, employees of the Calumet & Hecla and subsidiary companies received the following notice, according to the *Houghton Mining Gazette*:

Beginning August 1, 1913, and until further notice, the Company's employees' aid fund will pay to members injured on and after above date, while at work in the employ of the company, \$1 per day for each working day, beginning with the sixth working day, during disability from such injury or until payment under the Employers' Liability and Workmen's Compensation Act begins. Provided such disability is not caused by wilful misconduct or gross carelessness of the injured employee. Where disability lasts more than eight weeks, the Act provides for compensation from the day of the injury. Therefore, any member whose disability lasts more than eight weeks and who has been paid by the aid fund from the sixth day of disability to the date at which compensation under said Act begins, shall pay back to the aid fund a sum equal to that he has received from it.

The above payment of \$1 per day will apply only to members whose wages are more than \$30 per month; to members whose wages are \$30 or less per month, the payment will be 50c. per day.

Over 56% of the gold, or 98,779.72 oz., was derived from silicious ores; 39,010.52 oz., or 22.2%, from placers; and 34,200.83 oz., or 19.5%, from copper ores in Montana in 1912. The placer gold produced in 1912 amounted to \$806,419, of which \$710,387 was obtained by dredging. The gold won from placers in 1912 was \$121,618 more than in 1911, and that taken from the lode mines was \$206,954 less. The gold recovered from ore treated at gold and silver mills amounted to \$1,039,470, that from concentrates amounted to \$666,954, and that from crude ores shipped to smelters, \$1,109,255.

Gold-Milling in China

The illustration at the top, left, shows a Chinese gold-mill. The quartz has just been taken from the mine and is ready to be roasted in an open furnace. While the ore is still hot, water is thrown on it to assist in breaking it by hand before being fed to the mill. I have never been able to discover that the natives appreciate the effect which roasting has on sulphides. The baskets, shown in the picture, are used in carrying the ore from the mine to the mill. The right-hand picture shows the mill itself. This is usually operated by a mule or donkey, and the lower stone is slightly sloped toward the centre, so the pulp will not escape over the edges. The ore is fed dry and is not over 1-in. cubes. The lower stone is usually about 5 ft. in diameter, the roller about 2 ft. long, and from one to two feet in diameter. The roller revolves around a wooden post, set in the centre of the lower stone. The capacity of a mill is from 300 to 1000 lb. per day, depending on the hardness of the ore, size of the mill, and motive power. The ore is ground sufficiently fine to liberate the free gold it contains. After the ore has been ground in the mill, it is run over a shallow, smooth, inclined sluice, as shown. The water-supply is regulated so as not to move the pulp too fast, and the pulp is constantly being raked up the incline until it is well concentrated. The operation, in a crude way, resembles that of a Dorr classifier. The concentrate is panned for free gold in wooden pans, or in tin wash-basins, is then allowed to oxidize for a few months, and is panned again, and sometimes reground. The tailing is also panned. There is not much gold left after this process, and there are few, if any, Chinese tailing-piles waiting to yield a fortune to the cyanide man. The lowest picture shows open-cut and ground sluice in Chinese placer working. When washing gold-bearing gravel, a trough similar to the quartz concentrator is used to catch the gold.

The best known gold mine in China is at Chou Yuen, in Shantung, where some years ago ore carrying about \$10 was crushed by stamps, amalgamated, and the concentrate chlorinated, as was the practice in California until recently. At periods when the local farmers were not busy in their fields, it was their custom to purchase the tailing from the chlorination plant and carry it home for treatment.

Geology of the Kalgoorlie Goldfield—IV

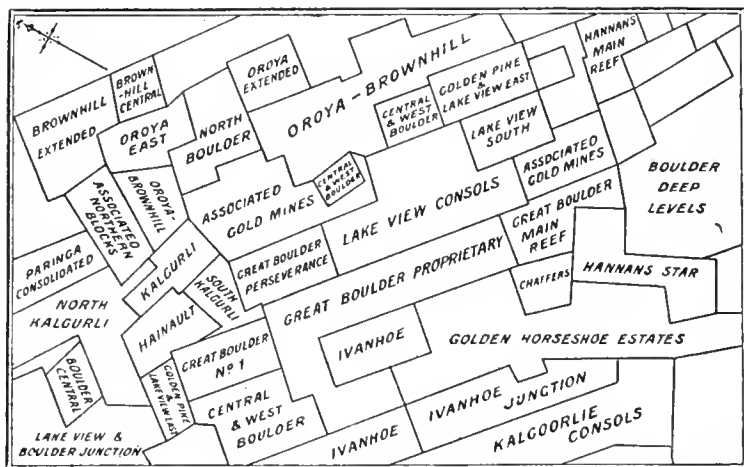

By MALCOLM MACLAREN and J. ALLAN THOMSON

The quartz-dolerite greenstone ('North End' type) is petrologically similar to those described in the previous article, but is somewhat more chloritic, and does not, so far as is now known, show any tendency to alteration to white or pink varieties. It may be concluded that it represents an original rock slightly more basic than the typical rock of the 'Mile' area. Its separation in this place is, on the whole, for economic rather than for petrological reasons. It carries no 'lode formations', and whatever gold has been found in it has been derived either from quartz veins or from secondary impregnations in the oxidized zone. This separation is tentative, for it is by no means clear whether its poverty in gold is due, as is probably the case with the quartz-dolerite amphibolites, to an influence deterrent to auriferous deposition and inherent in the 'North End' type, or whether it is merely

the Hannan's Reward mine, it lies again on the western side of the branch. To understand its origin, it is necessary to go a long way back in the history of the Kalgoorlie dike—indeed, to the time when it was still fluid. There were then local movements—currents, if such a term can be applied to anything so inconceivably slow as the translation of matter through the viscous mass—that, following the natural tendency of like elements to gather together, and guided by the convection currents due to unequal rates of cooling, took the basic elements toward the cooler margin of the type. The physical process of separation is closely akin to that of matte from slag pot or crucible. While the main mass of the Kalgoorlie dike became more acid (silicious), the western margin and the narrow portions of the northern branches became more basic than the original magma. On cooling, therefore, the greater

portion of the dike was a quartz-dolerite or quartz-gabbro, while the narrower branches and the chilled western portions formed a normal dolerite or gabbro and in special cases a hornblende dolerite. Later changes converted the more basic dolerites, after solidification, into amphibolites. The epidiorite and amphibolite rocks thus produced are unfavorable to auriferous deposition. Highly productive lodes, when pursued into amphibolitic rocks, become barren.

The quartz-dolerite amphibolite is easily distinguished in hand specimens from the quartz-dolerite greenstone. It is a coarse-grained dark green to greenish gray rock generally showing bright green cleavage surfaces of hornblende. Two varieties of hornblende are usually present: a bright

A PART OF THE KALGOORLIE DISTRICT.

accidental and is due to the great sheared zones which subsequently form the lode-channels having avoided these narrow tongues.

The Brownhill branch of the Kalgoorlie dike is regarded as being composed entirely of this rock, while it also forms a great portion of the Hannan's branch. In this western tongue the North End type of quartz-dolerite greenstone is, however, confined to a long narrow strip, about 300 yards wide, passing from the Sir John Forrest lease through Maritana Hill, Cassidy's Hill, and the Hannan's Reward leases to the Golden Zone and New Reefers leases. It may be looked on as a passage rock to the next type, and differing from the Boulder type simply in having cooled more rapidly and in having largely escaped alteration by vein solutions.

Quartz-Dolerite Amphibolite

This rock-type is, broadly speaking, developed along the western margin, or hanging wall of the main mass of the Kalgoorlie dike. Farther north it occupies the whole of the Hannan's branch from the Ironsides North to the Sir John Forrest leases, while still farther north, in the neighborhood of

green variety representing an original hornblende, and a pale hornblende representing an altered pyroxene. Felspar (albite) is often present in columnar crystals, but in many places the original felspar constituent has been scanty. Narrow bands (pegmatite) of coarsely crystalline minerals occur, especially west of Maritana hill (Mt. Gledden). In these the hornblende crystals are often greatly curved, giving a barrel-shaped appearance to large crystals on broken surfaces. A peculiar type of amphibolite shows, on broken surfaces, numerous large but indefinite shining faces which disappear on changing the angle at which the specimen is held to the light. These are termed 'lustre-mottled' amphibolites and are believed to be derived from an original hornblende dolerite. In most specimens the hornblende has been largely decomposed to chlorite.

Ultra-Basic Rocks

This series is best developed near Hannan's Lake, some distance to the south of the goldfield. Within the Kalgoorlie auriferous belt there are three areas underlain by rocks of this group, the internal rela-

tions of which are rather obscure. They comprise serpentine, a dense hornblende rock, talc-schist, and a coarse magnesian carbonate (magnesite) rock. The original rocks, of which the foregoing are merely alteration products, were probably augite-peridotite and pyroxenite. These are best regarded as basic segregations from the same deep-seated magma that furnished the material of the Kalgoorlie dike and that after some time followed it upward along the way already cleft through the Older Greenstones.

The three areas of ultra-basic rock appear to be resolvable into an eastern and a western band. The eastern band lies in the neighborhood of the Hidden Secret lease at Williamstown; the western commences north of the Great Boulder Northern lease, 147°, and runs north as a narrow band probably as far as and beyond the business portion of the Kalgoorlie township. Owing, however, to thick deposits of detrital matter, its width and extension is exceedingly indefinite. It contains the same rocks as the eastern band, but in it the massive hornblende rock is, so far as the band may now be examined, the predominant rock. It is a coarse rock made up of crystals of pale hornblende, weathering readily in dumps to a pale green mud. Good examples are to be found east and southeast of the Kalgoorlie power-station.

The eastern band is composed mainly of coarse carbonate (magnesite) rocks, massive hornblende rock, and talc-schist. Serpentine is not so common, owing to the fact that these rocks have rarely been penetrated below the oxidized zone, or if they have, the workings are now not accessible. Good examples of serpentine have, however, been obtained from deep bore holes from the Kapai lease, where the rock shows as a dense black rock with a characteristic fracture of serpentine.

Porphyrite

This rock lies in the west of the area where it apparently underlies the detrital deposits under the broad valley on the eastern side of which the townships of Boulder and Kalgoorlie lie. Exposures of this rock are few, the best and freshest rocks coming from the old water shafts at the foot of Brookman street on the Coolgardie road, from the old water shaft in the Kalgoorlie power-station yard, and from shafts south of Boulder City.

The porphyrite varies in color from dark green to light gray, but may nearly always be recognized in a hand specimen by the large well shaped crystals of dull white felspar scattered through the rock. Occasionally also fairly large crystals of hornblende are found. Some varieties, especially from the south, show black biotite mica certainly derived from the hornblende. These, as a rule, are all that may be determined in a hand specimen. The power-station rock closely approaches in structure a diorite, and is therefore best termed diorite porphyrite. Porphyrite is nowhere known to be auriferous in the Kalgoorlie area. The porphyrite dike is regarded as a further, later, and more acid emanation from the deep-seated magma that yielded the quartz dolerite and ultra-basic intrusions.

Albite-Porphyry

Numerous small dikes penetrate both the Older and the Younger Greenstones. These are all of one type. They are hard white or pink contact rocks, giving considerable difficulty from their hardness when met with in cross-cutting or sinking. They may be all classed as albite-porphyry, and regarded broadly as narrow tongues sent for the most part along the shear planes of Younger Greenstones from the large mass of felspar-porphyry to the south. The most important is certainly the Great Boulder dike, which proceeds from the main mass northward through the length of the Great Boulder leases and thence through the Western lease of the North Kalgurli ground. This dike dips to the west at a flatter angle than the Great Boulder lode channel, and is intersected by the latter at a depth of about 2250 ft. near the main shaft.

The Hainault porphyry dike runs northward from the Hainault area, splitting into two branches before it leaves that lease. One branch lies west of the Brookman's Boulder shaft; the other lies an equal distance to the east. The western branch continues immediately west of the Golden Gate shaft. Both branches dip steeply to the west. Southward from the Hainault the dike passes into the South Kalgurli ground, and thence probably along the eastern boundary of the Great Boulder Perseverance lease.

The Kalgurli porphyry dike lies to the east of the Kalgurli main shaft, passes north through the long southern tongue of the North Kalgurli, and has been traced as far as the smithy on the last named lease. Southward it has not been found anywhere on the surface, but it is probably the same dike that occurs near the west boundary of the Kalgurli at the 1000-ft. level; also west of the Australia East Lode at the No. 12 level of the Associated Gold Mines, and on the wall of the east lode in the lower levels of the Lake View Consols.

Small porphyry dikes are known on the wall of Morrison's lode, Hannan's Star, below the rich shoot of the Hainault, near the eclipse (Oroya Links) orebody; along the course of the Jasper lode, in the Ironsides North and Union Jack ground, and in the ultra-basic rocks east of the Golden Zone. They are certainly older than the period of ore deposition, but there is probably no connection between these intrusive porphyries and the orebodies, for there is evidence to the effect that the former had solidified and had even been faulted many feet before the passage of auriferous solutions. The walls or the immediate neighborhood of these dikes has, however, yielded occasional pockets of ore. This has been most notably the case along the course of the Kalgurli dike. The Great Boulder dike is a great development of graphitic schist, as this rock is here regarded mainly as a result of local shearing.

All the rocks are altered, but if an attempt be made to classify the rocks by the nature of their alterations, complications arise owing to the superposition of different alterations on the same rock. The important processes of alteration may be summarized as below:

- A. The formation of the amphibolites.
 1. Pressure alterations.

2. Contact alteration of the massive amphibolites.
3. Combined contact and pressure alteration producing hornblende schists.
- B. The formation of the greenstones.
 1. By juvenile processes acting on the original rocks.
 2. By incipient vein-alteration of the amphibolites.
 3. By ordinary hydrometamorphism of the amphibolites.
 4. Contact alteration of the greenstones.
- C. Vein-alteration.
- D. Pneumatolytic alteration.
- E. Formation of the jaspers and graphitic schists.

No attempt will be made here to review all of these processes and their results, but the alteration incident to the inflow of vein waters will be briefly described.

By vein-alteration is meant the alteration produced in rocks which are penetrated by veins or lodes carrying exploitable minerals by means of the solutions which brought the ores. The term seems preferable to that of 'metasomatic processes in fissure veins' if only because of its brevity. The rocks affected at Kalgoorlie are chiefly the older greenstones, the ultra-basic rocks and the quartz-dolerite greenstones, each of which will be considered in turn.

Vein-Alteration of the Older Greenstones.

In the immediate vicinity of the quartz-dolerite greenstones of the 'Mile', on their eastern side, there is a considerable development of a whitish grey fine grained rock, much traversed by small green veinlets, to which the field name of calc-schists was provisionally applied. These rocks must be considered as the vein-altered products of the older greenstones, for in the Eclipse mine they are restricted to the neighborhood of the lode, while chloritic rocks form the less altered country on each side.

The name calc-schist is in some respects a misnomer, for the rocks are more often massive than schistose, though after exposure to the atmosphere in a dump, they usually develop a latent schistosity. Besides the dominant carbonate, they contain small lath-shaped sericite bodies. The rocks are exceedingly dense, and a high power of the microscope is required to distinguish the individual carbonate grains, and to reveal the presence of the quartz between them. They differ from the older greenstones in the paucity or absence of chlorite, which when present occurs in larger flakes. Occasionally fairly large octohedra of magnetite are scattered through the rock.

In the schistose varieties the muscovite is no longer aggregated in pseudomorphic areas, but scattered promiscuously through the rock. Occasionally the carbonates show an individualization into relatively large rhombohedra. The rock is therefore a fine grained quartz-carbonate-sericite schist, differing from that derived from the quartz-dolerites only in its finer grain and in the larger proportion of carbonates. Occasionally the rocks are brecciated and cemented by material which consists in the middle of cherty quartz and on the outside of carbonates. The

vein-alteration, as compared with the older greenstones, consists chiefly in the elimination of chlorite. The relation of the calc-schists to the older greenstones is similar to that of the pink and white quartz-dolerites to the quartz-dolerite greenstones. The complete process, however, has converted a hornblende-zoisite-felspar rock into a quartz-carbonate-sericite rock.

Time has not permitted a thorough investigation of the gold deposits in the ultrabasic rocks of the 'North End.' The principal deposits appear to lie along zones in which the peridotites are replaced by rocks consisting chiefly of magnesite with subordinate talc, while these are separated by bands of talc-schists with subordinate carbonates, as well as by hornblende rocks after pyroxenites. It seems logical to conclude that the talc rocks represent an incipient vein-alteration, and the magnesite rocks the complete alteration.

Vein-Alteration of the Quartz-Dolerite Greenstones

As already stated, the rocks described above as non-chloritic or 'pink and white' quartz-dolerites, must be regarded as arising from the quartz-dolerite greenstones by vein-alteration. The lode-matter itself largely consists of this kind of rock. Moreover, though not restricted to the neighborhood of the lodes, and not invariably forming the walls, the white and pink rocks invariably contain at least a low gold tenor, while the chloritic rocks are seldom auriferous. Finally, it is impossible to imagine the deposition of the tellurides from solutions that did not have a marked action on the country, and these rocks are the only ones that can be considered as vein-altered.

The vein-altered rocks from the 'Mile' have already been described; those of the 'North End' present some features calling for notice, and will here be briefly described. In hand-specimens the chief differences are the absence of magnetite or hematite, and the presence of abundant large cubes of pyrite. Very often the change from the green rock to the white may be observed in the space of a few inches on each side of small quartz veins. Near the vein the rock is studded with crystals of pyrite, which diminish in size and abundance with increasing distance from the vein, and finally disappear at a distance of 1 to 3 in. With the development of the sulphides there is a corresponding loss of green color as the vein is approached. Simpson has noticed this sulphide-bleaching, and ascribes it to the formation of pyrite at the expense of the iron in the rock-silicates. The bleached rock is much carbonated and sericitized, and is practically free from chlorite, confirming Simpson's explanation. The quartz veins which brought the sulphur are themselves free from pyrite. A similar but less intense impregnation of the rock with sulphide, accompanied by a more extensive bleaching, is noticed on each side of small veins of quartz and albite.

With the exception of these peculiarities, the vein-altered rocks of the 'North End' are similar to those of the 'Mile,' although there is not so extensive a development of them. The most characteristic feature of the rocks of both localities is the part or

complete removal of ehlorite, or its replacement by sericite and carbonates. Corresponding to this the analyses show a slight dehydration. In the much altered rocks the leucoxene is replaced by rutile and carbonates and the ilmenite by pyrite. In some cases there appears to be an introduction of iron, resulting in the formation of magnetite or hematite. Corresponding to this, veinlets of quartz, siderite, and micaceous hematite are of frequent occurrence.

Since albite is found in these rocks as a vein-mineral, it follows that it must have been stable under the conditions of the alteration. Most of the rock feldspars are sericitized, but occasionally they are remarkably clear and free from inclusions. It is seldom possible to demonstrate that newly formed albite is present in the rock, but possibly in many cases the older crystals have been 'healed' by the filling up of cracks and cavities with fresh albite. Beyond perhaps a substitution of sericite for the chlorite enclosed in the feldspars, sericitization cannot be claimed as a marked feature of the alteration. In the schistose rocks now to be described, however, the feldspar has completely disappeared.

Local Shearzones

Probably coincident with the intrusion of the granite and resulting from the pressure thus exercised upon the greenstone buttresses there were developed in them local shearzones striking N.N.W.-S.S.E., and coinciding therefore, as might be expected, with the natural planes of weakness, those of the foliation of the Older Greenstones and of the intercalation of the Younger Greenstones. They were, however, local and would not be worth mention were it not that they served in the immediate neighborhood of Kalgoorlie as channels for the passage of auriferous solutions and for the deposition of gold. Elsewhere in the area and especially near Coolgardie, gold was deposited at or near the contact of granite and greenstone or at or near the contact of pegmatite or quartz-porphyry dikes—tongues from the granite mass—with greenstone. Elsewhere also gold is associated only with the quartz veins developed near these contacts; at Kalgoorlie, by the accidental intermingling of gold and telluride solutions, it has been deposited as 'lode formations' along these shearzones.

Subsequent to the deposition of gold there has been little movement in the region. Horizontal earth pressure has generated several series of over-thrust faults. The most important series has an east and west strike, and the position of the various members of this series is best indicated by the irregularity of the contact of granite and greenstone near Coolgardie. Within the greenstones, owing to the lack of outcrops, they are difficult to trace. One thrust-plane may, however, be made out passing southeast from Mt. Robinson to a few miles south of Feysville (where the shearing that accompanied it is quite evident) to Mt. Monger in the southeast. The pressure generating this over-thrust was horizontal and from the south. Other minor faults of compression (reversed or over-thrust faults) are known, but are comparatively small and are only important where they disturb the auriferous lodes.

Regional Movements

Here, then, was the end of the internal history of the region. During all the eons that have passed since that day it has been above sea-level, perhaps oscillating gently up and down. There is no evidence that it has ever dropped below sea-level, but its history during Paleozoic and Mesozoic times is a sealed book. The northern portion of Western Australia was submerged during part of the Paleozoic age, the coastal portion in the Mesozoic age and southern portions in the Cenozoic age, but there remains no trace whatever of submergence in the central area nearer than Lake Cowan (Horseman), 90 miles to the south of Kalgoorlie, where Tertiary marine shells have been found.

A dry land may therefore be postulated in the Kalgoorlie area during the whole of measurable geological time. And since land above sea-level, when not being preserved by the deposition of a protecting blanket of alluvium, is being subjected to the unceasing onslaught of wind and rain, it will in course of time be degraded nearly to sea-level, provided that the loss caused by denudation is not compensated by a regional uplift. The absence of marine deposits on the central plateau indicates that this compensating action has taken place, and therefore that the amount of denudation has been great. The matter is by no means of academic interest alone, but is of vital importance from an economic point of view. If the orebodies at present worked at Kalgoorlie were deposited near the surface they must be expected to be richer than any to be found in future depth. If they were deposited 2000 or 3000 ft. below the then existing surface they undoubtedly are primary deposits, and local enrichments such as that known at Kalgoorlie at and below the 2000-ft. level may be expected to recur as far as mining may be carried in depth. It is here assumed that the deposits now being worked are primary and that they were deposited far beneath the original surface.

Geological Relation of Auriferous Occurrences

Before leaving the consideration of the area included in the above sketch, it will be of interest to describe the geological relationship of its gold deposits. The principal fields are Kalgoorlie and Coolgardie, with outlying camps at Burbanks, Bonnievale, Kunanalling, Kintore, Black Flag, Feysville, Mt. Monger, Bulong, Boorara, Balagundi, and Kanowna. With two exceptions Boorara (golden ridge) and Balagundi, and these exceptions may be only apparent, for time has not permitted of a close survey of either field, gold occurrences lie either at or near the contact of granite and greenstone or at or near the contact of porphyry and porphyry dikes and greenstone. The occurrences near granite porphyry and quartz-porphyry dikes are closely allied to those at granite contacts, since the dikes may be regarded as tongues from the Coolgardie granite. Examples of these at granite contacts are Lord Bobs, Bonnievale, Kunanalling; and at pegmatite, granite-porphyry, and quartz-porphyry contacts are Londonderry, Burbanks, and Coolgardie. At and near feldspar-porphyry contacts are Kalgoorlie and Kanowna, while Bulong and Feysville are in or near

porphyrite. There is thus a constant association with the more acid intrusive rocks. It is difficult to conceive the actual relation. It is certain that the auriferous solutions appeared after the solidification of the dikes and it can only be suggested that the auriferous solutions were associated with the more aqueous and more silicious residuum of the magma from which the granite and quartz porphyry has been derived.

The relationship has been observed in far too many cases, not only in the area dealt with, but also in other fields in Western Australia, to be accidental, and it may be laid down as the first general axiom in prospecting in Western Australia that search for auriferous deposit should be conducted near contacts of granite and greenstone or of porphyry dike and greenstone. The latter for preference. As bearing out the hypothesis that auriferous solutions are associated with the silicious and products of an acid magma, general experience has shown that the largest and richest gold deposits are not associated with the strongest porphyry dikes. They rather seem to occur (as in the case of the Hainault orebody, Kalgoorlie) just above or beyond the point where a dike runs to a feather edge. Only very small dikes are found near the Great Fingall lode. It therefore follows that most important dikes, from an economic point of view, may never come to the surface. They may be 'blind' dikes. For this reason and since these are most likely to be found on the margins of the greenstone belts, these margins must be carefully searched for a long distance, a mile or even more, from the granite contact. Every contact does not carry gold, but the area likely to repay careful prospecting is greatly restricted when the above considerations are taken into account. It is not too much to say that had a geological map showing all the porphyry and porphyrite dikes of the region been available in 1893 every deposit now known, and some still unknown, would have been discovered within three months, and thousands of pounds worth of useless work and misspent energy avoided.

Mining in Mongolia

In an excellent review of 'Russia in Mongolia,' the *Far Eastern Review* contains the following notes on the mining industry of that country:

The mineral wealth of Mongolia is at present practically undeveloped, but from a geological examination, and from reports from prospectors during the last few years, it appears to be of great value, especially in the north. In addition to salt, coal, and marble (a small quartz crystal used for the manufacture of spectacles is quarried at five 'marches' from Kalgan) the chief development is being carried out by the Société Mongolor. This private company was formed by a G. Victor van Grotte, of the Imperial customs service, to work a mining concession in Mongolia, and for many years proved a failure. Gold was there in workable quantities, and American engineers and machinery were imported. In 1910 the mine paid 150%, and in 1912 a payment of 300% was hoped for. The Company is at present working seven mines, and employing

upward of 7000 Chinese coolies—who work under the usual Chinese method—the Company supplying all gear and the gangs of coolies under the foreman selling all gold found at a fixed rate to the Company, \$20 per oz. The Chinese authorities, until quite recently, had at each mine a small guard and an official, who checked the tax payable by the Company on the amount of gold excavated.

New English and American machinery was recently imported, and Mr. Henson, a German, acted as chief engineer and assistant to Mr. van Grotte. A new electric plant for refining the gold has been installed. It is said that the River Yere contains a great deal of gold, and dredging operations have already been commenced. All the directing staff are now Russians, and a number of Russian prospectors are employed in prospecting the valleys. There is a considerable mortality among the Chinese coolies from a mysterious disease. They catch it from the water, and it affects their limbs, in most cases proving fatal.

In addition to gold, there is to be found lead, silver, iron, and zinc, but as yet no attempt has been made to mine these minerals.

Radium Ores in Australia

The Radium Hill mine, near Olary, South Australia, was recently examined by H. Jones, inspector of mines, who made the following report:

A large amount of good development work has been done at different points on the property. Five underlay shafts have been sunk to various depths of from 70 to 100 ft.; driving and stoping has been done in the lode formation at the 60-ft. level, and considerable amount of the lode material extracted from the various workings, crushed and concentrated by the magnetic separator at the mine, and the various grades of concentrates obtained, amounting to 10 tons per week, have been forwarded to the Sydney works for further treatment. Driving and stoping is in progress at the 25-ft. level in No. 2 shaft; the southwestern drift is in a total distance of 31 ft.; the formation disclosed in the workings is from 2 to 4 ft. wide, of schist and iron veins, with incrustations of carnotite through the matrix. The drift northeast, opposite the last one, has been extended in the orebody a distance of 30 ft., and at that point in the drift a small fault in the country occurs, bearing east and west and dipping at an angle of 45°. The fault apparently makes a clean break in the formation of several feet to the east; on the north side of the break (or displacement) two underlay shafts have been sunk in fairly good ore to a depth of 70 and 100 ft. respectively. This proves that the formation has not been disturbed to any great extent by the fault, and that the main orebody continues to extend in a northeastern direction. The plant on the mine consists of rock-crusher, rolls, magnetic separators, one petrol and one oil engine, all being housed with strongly constructed wood and iron buildings, and everything appears in good order for carrying on the work of crushing and concentrating the ore.—*Australian Mining Standard*.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Mining Reports

The Editor:

Sir—Some time ago, a report that was stated to have been the result of an examination made upon a mining property located on the vein formation of the famous Mother Lode of the western foothill region of the Sierra Nevada of California, came into my hands and has been carefully preserved by me as a classic. That it is unique among many documents pertaining to mines and mining situations, a perusal of the following excerpts from the text will convince any fair minded unbiased mining engineer. Certainly in part it is too good to keep, and in a spirit of benevolence and as an offering upon the shrine of professional goodwill toward professional brethren, the following extracts have been exhumed from their obscure place of burial among files containing many another mining report that is less picturesque, less unique. The following contains the rich kernel removed from the enclosing shell.

Value of Orebody.—In sinking the 110-ft. shaft and a small amount of lateral work, \$8000 in massive gold was obtained. By measuring the amount of ore removed, this gives a value of \$10 per ton in massive gold, and from the assays, the ore left standing averages \$1.60 per ton, making a total of \$11.60 per ton for the total block of ore (the italics are not contained in the original). which is 150 ft. long, 100 ft. wide, and 110 ft. deep. Owing to the noted uniformity of Mother Lode veins this block of ore can safely be assumed as developed, but due to the fact that the gold occurs massive there is a factor of chance that can only be assumed, hence using a factor of two we have a value for this block of ore of \$5.80 per ton. Treatment charges would be: milling 50c. and mining 50c. The extraction would be 90%, giving a net value of \$4.32 and a total value of \$475,200.

Probable Value.—Assuming that the vein will continue to the 200-ft. level and 100 ft. wide and 500 ft. long with an average assay value as shown to be \$1.30, or a net value of 55c. per ton, the treatment charges being: milling 50c. and mining 25c., with an extraction of 90% there is a probable net value of \$935,550. Or more probably, assuming the average value of the Mother Lode mines of this district of \$4.60, with the same charges and savings, will give a probable net value of \$6,719,000.

Possible Value.—Should the vein continue to the 1830-ft. level or more, as in the — mine, or to the 3254-ft. level or more, as in the — mine, and average value of the other mines of the district, this mine would yield a profit anywhere from \$30,000,000 to \$100,000,000. The mine is not far enough developed to justify these assumptions as positive, but—and here let the report conclude with that reassuring, inspiring, and valiant *but*.

How plain and simple it all is to write a mining

report. Not necessarily one that will ‘stick,’ but a picturesque and unique document that is readable and fairly well filled with data culled in a measure from geologic reports and folios of the region or from other vicarious sources and containing more or less uncertain assumptions and statements as to ore values and to positive, probable, and possible ore reserves that from their very artlessness and ingenuousness should convince, but which somehow fail to carry a satisfactory weight when their authors are brought ‘upon the carpet.’ And how many reports presuming to describe mining properties are written that should never have been penned—because of the wicked waste of ink resulting therefrom.

WILBUR E. SANDERS.

Sonora, California, July 6.

The Possibilities of Grinding Pans

The Editor:

Sir—the article on ‘Grinding Pans at Kalgoorlie,’ by M. W. von Bernewitz, in the *Mining and Scientific Press* of May 17, is particularly valuable on account of the fact that the literature on the subject of pans is meagre. Analysis of the table given in Mr. von Bernewitz’ article, however, does not seem to bear out the statements of Kalgoorlie operators that pans can hold their own against tube-mills, if they are to be regarded as sliming machines. Only the sizing through the 150-mesh screen is given. In comparing a pan with a tube-mill, it must be borne in mind that in an all-sliming plant the oversize from the tube-mill generally goes to a classifier, which returns it to the mill, and does this as many times as necessary for sliming. It therefore seems just, in estimating the capacity of either machine, to take into account only the ore reduced by it to slime, which is here considered as all the material passing the 150-mesh screen.

I herewith reproduce the part of Mr. von Bernewitz’ table referring to the 5-ft. pans, and add the last two columns which I have computed from his figures.

Name.	Feed -150, %.....	Discharge -150, %..	Daily capacity, tons.	Feed slimed, %.....	Actual daily cap. in slimed prod., tons
Grinding roasted ore:					
1. Associated	47	85	9	38	3.42
2. Associated Northern..	45	85	7	40	2.80
3. Boulder	70	90	7	20	1.40
4. Kalgurli	47	80	11	33	3.63
Grinding roasted concentrate:					
5. Hainault	29	94	24	65	15.60
6. Horse-Shoe	36	94	24	58	13.92
7. Ivanhoe	46	94	12	48	5.76
8. Lake View & Star....	46	94	12	48	5.76
9. Oroya Links	46	94	12	48	5.76
Following stamps:					
10. Hainault	36	52	16	16	2.56
11. Ivanhoe	36	52	15	16	2.40
12. Lake View	39	60	13	21	2.73

Comparison of 3 with 1 and 4 seems to show the bad effect of having slime in the feed, the slime probably having a lubricating effect in lessening the attrition among the particles of sand. However, the extremely low capacity of 3, only 1.4 tons per day, may in part be due to an insufficient amount of coarse feed. The greater capacity of 5 and 6, 15.6 tons and 13.92 tons, respectively, each taking a feed of 24 tons, seems to indicate that with proper feeding a fair capacity could be attained, but the nature of the material in the feed undoubtedly has a considerable effect on the tonnage, as exemplified by the capacity of 7, 8, and 9.

Mr. von Bernewitz states that the amount of water with the feed must be carefully adjusted. This is probably as important as in tube-mill practice. Will Mr. von Bernewitz or some Kalgoorlieite be so kind as to tell us the amount of moisture in the feed that experience has shown to give the best results.

I have often wondered whether a pan, on account of its low initial cost and the small time lost in re-shoeing, might not be advisable in small mills doing all-sliming, but results at Kalgoorlie do not seem to give much ground for hope in that direction.

JOHN RANDALL.

Atlantic City, Wyoming, July 28.

The Editor:

Sir—In reply to John Randall’s queries concerning grinding pans, I would say that No. 5 column in his table is not correct, No. 3 from my original

mesh sereens, 47% of which will pass a 150-mesh screen. After roasting, it is mixed with weak solution and fed into 20 pans, the average slimed product being 85% through 150 mesh. Now 47% of 350 original tons is 164 tons, which requires no grinding, leaving 186 tons to be ground by 20 pans, which is 9.3 tons each per day, as shown in my table, where I gave the nearest whole number.

I certainly agree that it is best to classify before grinding, and then the pans would show a better result, as is evident at the Kalgurli, where this is done. But with certain Kalgoorlie ores, after roasting, lime compounds greatly hinder the work of classifiers, so all the pulp is run through the pans.

I can assure Mr. Randall, in answer to his last paragraph, that the pan is an excellent machine, and I would certainly advise its installation in a small mill where the expense of a tube-mill was not justified. A pan could be arranged in closed circuit similar to a tube-mill, if necessary, and would show high results. Regarding the percentage of moisture in the pulp for pans, this can only be judged by the general character of the pulp and by screen tests of the overflow. Where the average moisture of tube-mill pulp may be 40%, the pan may have anywhere from 1½ to 4 of water to 1 of ore.

A table on pans was compiled in 1909 by Harley B. Wright, of the Perseverance mine, showing their performance at six mills at Kalgoorlie.

In conclusion, I would say that I am sorry that Mr. Randall drew an incorrect view of the excellent pan practice at Kalgoorlie, where, with several

Data.	Perseverance	South Kalgurli	Boulder	Associated	Kalgurli	Assoc. Northern
Monthly tonnage, 30 days	19,000	9030	18,000	11,600	10,700	3700

KALGOORLIE, WESTERN AUSTRALIA

DIAMOND-DRILL RESULTS AT FRASERS MINE.—THE HOWE VOLATILIZATION PROCESS.—NORSEMAN DISTRICT.—DEVELOPMENT OF PRODUCER-GAS PLANTS.—THE VICTORIOUS, BULLFINCH, AND PARINGA MINES.

The government mining engineer, Alexander Montgomery, has stopped the first bore on Frasers mine at Southern Cross, at a depth of 1160 ft. From 538 to 542 ft., the bore passed through 4 ft. of ore assaying \$20.26 per ton. From 958 to 976 ft., ore was again found, and the core at 968 ft. carried visible gold. From 1087 to 1100 ft., the main lode on the property, in Mr. Montgomery's opinion, was passed through. No assays of these two last developments have so far been published. The machine has now been moved 180 ft. south, where the second bore will be put down at an angle of 80°, so as to cut straight across the lodes. In this bore the lodes are expected to be found at shallow depth, as the site is nearer the outcrop. W. J. Loring has taken an option on the property with a view to forming a company in London.

The new volatilization plant, erected on the Gwalia Consols, is now treating 30 tons of ore per day, and the first return is awaited with interest. Ben Howe, who has devised the process, is confident of success, and states that the process is ideally simple, and a high extraction, 90% or more, at a low working cost, is certain. The latter depends on the price of salt, and the percentage required to volatilize the gold. Originally 5% of salt was the figure given by Mr. Howe, but he has since reduced it to 2%. The ore is refractory, and contains antimony and arsenical pyrite, and the successful treatment of such ore will open up vast possibilities not only in Australia, but all over the world.

The Norseman district has been under a cloud for years, owing to a barren or impoverished zone intruding at a depth of 400 to 600 ft. and causing the premature abandonment of many mines. In 1901, the Norseman Mines, Ltd., a London organization, secured \$5 for \$5 subsidy from the Government to sink the main incline shaft on the Viking mine from 450 ft. to a total depth of 700 ft. After sinking to 574 ft., work was suspended, and the mine shortly after abandoned after producing \$1,105,000 gold and \$15,000 silver from 56,000 tons of ore. A local syndicate re-staked the lease in 1906, and has since won \$417,300 from 11,000 tons from the shallow ground. Recently work was started at 574 ft., and after sinking to 600 ft., phenomenally rich ore was found, the first 3 tons broken being estimated to contain \$30,000, or \$10,000 per ton. The lode is now being opened at 600 ft. and further development should prove interesting, especially as the Government is prepared to subsidize boring in any district to the extent of \$2 for every \$1 local residents are prepared to speculate in diamond-drill work.

A great impetus has recently been given to producer-gas plants by the introduction of the Cambridge wood-burning generator, in lieu of the charcoal-burning generator previously in use. Charcoal in Kalgoorlie costs \$14.16 per ton, against \$3.12 per ton for wood, and, as firemen, certificated engineers, and water consumption are practically eliminated where producer gas replaces steam, the cost of power is reduced 70 to 80%. As a consequence, all the recently erected treatment plants, such as those on the Mountain Queen, Queen of the Hills, Yuanmi, and Victorious are operated by producer-gas plants. Since the advent of the Cambridge gas generator, Degenhardt and Jordan, of Bewick, Moreing & Co., have patented the Commonwealth down-draught wood-burning generator, and is claimed to be an improvement. This generator is now in operation on the Yuanmi mine, and is said to save \$425 per month on a plant treating 5500 tons, or 77c. per ton. A similar generator is to be installed immediately on the Sons of Gwalia in place of the Thomson-Houston charcoal generator, which only started running in October 1912. In addition, a larger Commonwealth generator, together with a 650-hp. gas engine, has been ordered and will operate the

vacuum-filter plant to be installed to re-treat the 2,000,000 tons of old residue now accumulated at the Sons of Gwalia mine. The first producer gas tried in Kalgoorlie was at the Great Boulder mine some years ago, for firing the Edwards roasting furnaces, but was not suitable for this purpose. Since then, however, this type of engine and generator has been vastly improved, and before long will probably completely supersede steam plants for operating all surface treatment plants.

G. M. Roberts, general manager of the Associated Northern, is very sanguine of the No. 5 level of the Company's Victorious mine, at Ora Banda, proving a success, because of the high average gold content obtained in the four winzes below No. 4 level. From west to east the gold content is as follows: \$31.80, \$9.64, \$31.44, and \$40.80 per ton. The lode ranges from 48 to 80 in. The winzes cover a distance on the ore-shoot of 173 ft., and the two end ones are the richest. The ore-shoot at No. 4 level is 250 ft. long. The station on No. 5 level is already completed, and the lode is expected to be cut in 20 to 30 ft. from the end of the station.

The Bullfinch management has at last published an estimate of ore reserves of the mine, and gives the figures as 158,300 tons assaying \$12.42 per ton above the 210-ft. level. The additional 5 stamps and tube-mill have been erected and will start as soon as the necessary motor arrives from England. Then 6000 tons monthly will be treated. The mine is proving irregular in gold content, but until more development has been done it is impossible to say how the mine will open. The lode has resumed its original strike of northeast and southwest, and is not nearly so rich as it was in the bend where it took a sudden turn to the west. The Corinthian North, under the same management, has published its first return as 4209 tons for \$13,400, with \$22,300 remaining in the residue. A vacuum-filter plant has been ordered and is expected to start in August, with a monthly capacity of 6000 tons.

The Paringa company, Kalgoorlie, recently started driving north on Geach's lode, 125 ft. west of the south shaft at the 100-ft. level. After going through 70 ft. of barren rock, 70 ft. of ore, varying in width from 36 to 60 in., assaying \$20 per ton, was passed through. The lode then increased in width to 84 in. and for the next 12 ft. assayed \$44 per ton. A start has been made to drive north at the 200-ft. level, and the first 12 ft. driven is in unprofitable ore. This west lode has never been previously worked in the property, and still has possibilities, though in the adjoining Associated Northern, the ore-shoots proved too short to be of any great permanent value.

The June gold return for the state of Western Australia was \$2,340,050. The principal producers are as follows:

Name.	Tonnage.	Value.	Profit.	Dividend.
Great Boulder	18,590	\$240,480	\$118,900
Ivanhoe	20,538	192,300	70,100

BOSTON

HOLDINGS OF FIRST NATIONAL COPPER CO.—ARIZONA COMMERCIAL COMPANY'S POSITION.—EAGLE & BLUE BELL DIVIDEND.

The announcement by the president of the First National Copper Co. that operations are to be resumed, and that a new process for the treatment of ores is to be installed at the properties in Shasta county, California, is of more than passing interest here, as by far the largest number of shares of this Company is held here in New England. There have been so many disappointing developments at the First National property, however, that while Boston is hopeful of success for the new venture, it prefers rather to reserve judgment for the present. The definite action taken by the management of this Company for rehabilitation, taken together with the marked success attending the developments at the Davis-Daly property, leaves only the Ohio Copper Co. now to work out its salvation to have brought back into the fold three of the favorites of the local coterie in the boom times. Ohio, while it is earning between \$15,000 and \$20,000 per month, seems able to make but little headway, due to the excessive tax of 15c. per ton being levied on the Company's shipments by the Bingham Central Railway Co., controlled by F. A. Heinze.

The Arizona Commercial property seems to be making fairly good progress under the new management, headed by C. S. Smith, who is also president of the adjoining property, the Old Dominion. According to the annual statement of the Company, just issued, there was \$153,000 on hand on June 20 last, with total quick assets in excess of \$193,000. This is against an indebtedness of \$14,700 at the close of the previous year. The new Company, when it was formed, levied an assessment of \$3 per share, which is exactly the price for which the stock is selling in the open market at the time of writing. Mr. Smith, while not inclined to bolster the hopes of stockholders, issues a frank statement, in which he says that shipments under the 20% leasing system were discontinued on January 1 of this year, because of the tax laws enacted by the state of Arizona. Small stringers of ore have been found and it will be the policy of the Company to follow these up in the hope that they will lead to a body of commercial ore.

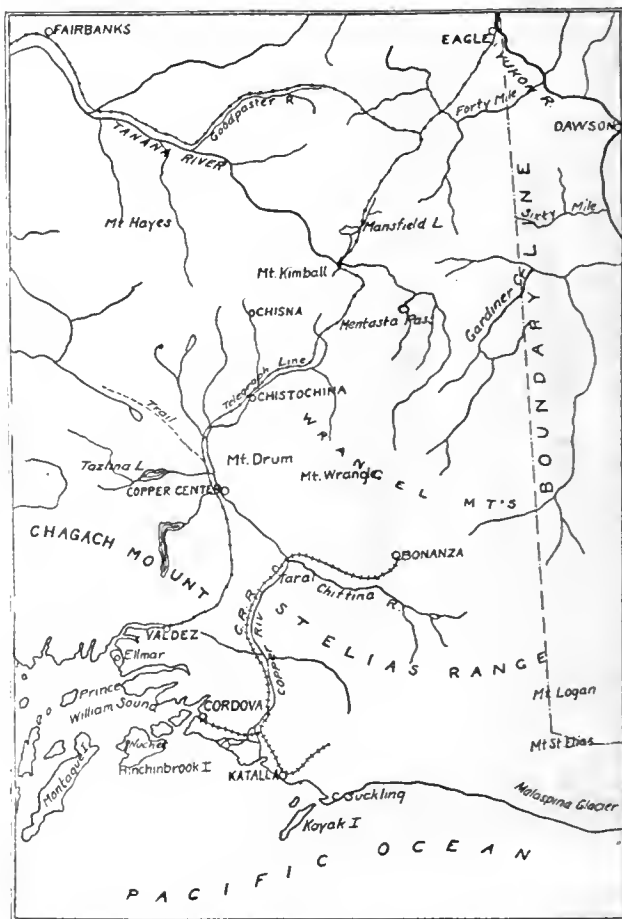

The action of the directors of the Eagle & Blue Bell Mining Co. in paying the third 5c. dividend for this year was well received here. This dividend on the \$893,146 shares of stock called for the disbursement of \$43,657 and brings the total payments for the year to date to \$133,972.

SOUTHWESTERN ALASKA

THE NEW GOLD PLACERS ON THE SUSHANNA RIVER; HOW TO GET THERE, AND VALUE OF THE GROUND OPENED.—CONDITIONS IN SOUTHWESTERN ALASKA.

The latest reported discovery of placer gold has been made on the Sushanna river, and stampedes of considerable numbers of placer miners and others have taken place from Seward, Valdez, and Cordova, as well as from points along the Copper River & Northwestern railroad. This is the best route to take to the new 'diggings' for anyone going in from the coast, as the Sushanna river is in that part of Alaska hitherto unexplored near the headwaters of the Tanana river. Kennecott, the northern terminal of the Copper River & Northwestern, is reported as being the best starting point for the creeks on which discoveries have already been made, which are 90 miles distant from that place. From the latest telegraphic reports, Dawson and other towns on the Canadian side are also furnishing their quota of stampedes, these going in by the way of Kirkham Landing with horses to the White river, and pole up that to the mouth of the Snag, then 'mush' overland to the diggings, a total distance of 260 miles from Dawson. Several creeks have already been staked, and Alex. Walstrom and John Linquist write that the former took out pans that yielded as high as \$4 and \$5 per pan, and that on No. 6 Above, on Bonanza creek, two men are said to be taking out \$2500 per day. Laborers

are receiving \$12 per day, and as bedrock is reported to be shallow, only from 1 to 5 ft. of gravel lying above it, shoveling is comparatively easy. These reports were brought down to McCarthy, on the Copper River railway, by two returning miners named Jim Morris and Dan Stacey, who also state that the trip in at this time is quite difficult owing to the high waters in most of the streams. The latest news from Dawson with regard to these discoveries is vouched for by Fred Best, a partner of Billy James and Nels Nelson, the actual discoverers, who has just returned to Dawson, having 'mushed' across the country to the head of the White river, then down the river in a small boat. He says that the Discovery stream, known as Bonanza creek, seven miles long, and a tributary known as Eldorado, four miles long, had all been staked since May last when the discovery was made, and that now prospectors are staking on Coarse Gold creek, Money gulch, Gold Run, and Wilson creeks, all of which carry pay from the grass roots, and the gravel is thawed and there is

SHOWING COUNTRY AROUND NEW PLACER DISTRICT.

plenty of water for sluicing. Mr. Best advises that any prospectors going in should take a full winter's supply, because the 'camp' is at the head of the highest watershed, and the winter snows are extremely deep, so that the trails are almost impassable. The new discoveries are on the American side, 30 miles from the international boundary.

Should these new discoveries prove to be as valuable as is claimed, they will be of great benefit to southwestern Alaska, owing to the present conditions there, the tying-up of the coal lands as well as the recent tying-up of the Alaska Northern railway for failure to pay taxes. This portion of Alaska has for some years past proved to a great extent disappointing, so far as attracting capital or new arrivals is concerned.

Despite the fact that during the past three years the copper mines on Prince William sound and in the Copper River district have been producing a greatly increased tonnage of copper ore, and the further fact that the free-gold quartz mines on Falls creek, 26 miles from Seward, also in the Willow Creek district, about 40 miles from Knik, at the head of Cook's Inlet, the Cliff mines near Valdez are producing bullion on a satisfactory scale.

NEW YORK

ORGANIZATION OF THE CIENEGUITA CONSOLIDATED MINES.—MESSINA MINE DEVELOPMENT AND PRODUCTION.—SANTA GERTRUDIS.—FORGED NORTH STAR SHARES.—OHIO COPPER.—MINERALS SEPARATION AND BUTTE & SUPERIOR.

By the reorganization of the Cieneguita Copper Co. and the Cieneguita Securities Co. under the name of the Cieneguita Consolidated Mines, a Mexican property with a shady past re-enters the paths of virtue. The Company was organized 12 years ago with an authorized capital of \$10,000,000. Then followed years of high finance that led to the existence of three companies of the same name organized in different states, and finally to the appointment of a receiver in 1910. The Company owns 1100 hectares in Sonora, about 40 miles southwest of Sahuaripa. Such development work as has been done consists chiefly of adits which have disclosed fair quantities of ore containing $2\frac{1}{2}\%$ copper and 45 oz. silver per ton. The plant, including a small smelter, was poorly built, and transportation facilities to the property are not good. But the property has some promise, and under the new management may make a much better showing. The new board consists of James F. Whitney as president; Frank Fitz, formerly the superintendent, as vice-president; and R. C. Davenport, formerly the treasurer; Theodore Martin, a Los Angeles lawyer; G. D. Christy, a Phoenix banker; R. W. Campbell, who is a son-in-law of E. H. Gary; and David Angus, a New York contractor, as directors.

The Camp Bird management is highly pleased by the results being attained at the Messina, in Africa, according to a report made by the manager of the London office of Catlin & Powell. During June the output of concentrate by the Messina Development Co. was 486 tons averaging 38.6% copper, and 289 tons of middling averaging 11% copper. During the month 497 ft. of development work was done, the east winze from the No. 2 level disclosing 8.6% ore, the west raise from the No. 6 level showing 11.7% ore, and the east raise showing 8% copper ore. The railroad and reduction plant are expected to be finished within a few months. At the Santa Gertrudis, work has been hampered by a shortage of labor and lack of power following a dry season, and ore from the upper levels, which is lower grade, has been milled during the month. It is hoped that normal conditions will be restored during the next two months. Negotiations for taking over the Campo Morado have not been completed. It is rumored that negotiations for another property are also in progress.

Tonopah shares, which had been vigorously traded in on the Curb market recently, experienced a serious bump when it was discovered, early last week, that a considerable number of the share certificates of Tonopah North Star which had been traded in were forgeries. In the resulting excitement it was reported that hundreds of thousands of fraudulent certificates had been sold. Actually, however, between 7000 and 10,000 were sold by a man who used the name of Wells and also that of Ehrich. The certificates were lithographed and the signatures forged, that of Herman Zadig being especially cleverly written. As a result, the shares declined considerably in value, and other Tonopah shares also declined in sympathy. It is reported that negotiations are on for the merger of Montana-Tonopah and North Star, but it seems at least doubtful if so good a property as Montana-Tonopah would go into double harness with a property that has a bar sinister in its escutcheon, on the basis of present share values, at least.

Trouble seems to be brewing in Ohio Copper, and M. W. Atwater has been sent to make a complete examination. It is understood that if this is unfavorable, Al. Frank, the manager, who is regarded as F. A. Heinze's representative, will be displaced. June profits were only a few thousand dollars. The suit over the Hyde process at the Butte & Superior has been decided in favor of the Minerals Separation, Ltd., but the amount of damage has been left to a master. The decision will probably be appealed, but now that the Minerals Separation has legally established the fact that this is an infringement, the two companies are likely to come to a settlement.

LONDON

DEVELOPMENT AND PROSPECTS OF THE RHODESIAN HOLDINGS OF THE CONSOLIDATED GOLD FIELDS OF SOUTH AFRICA SUBSIDIARY COMPANY.

The ventures and investments of the Consolidated Gold Fields of South Africa in America have recently been recorded in the *Mining and Scientific Press*. It is opportune therefore to give the latest news of the Company's operations in Rhodesia. This work is conducted through the medium of a subsidiary called the Gold Fields Rhodesian Development Co. In the early part of 1912, the assets of the Rhodesia Exploration & Development Co. (the Sauer-Bailey control) were acquired in exchange for newly created shares. The issued capital now consists of 2,514,220 shares of £1 each, and the investments consist of shares in subsidiary and other companies originally valued at £2,856,337.

During the past year or so, the Rhodesian share market has been extremely dull, and the quotations have dropped seriously. Consequently the Company has been obliged to write down the value of its investments by no less than £508,296. Moreover, the market stagnation has prevented the raising of capital for the further financing of some of the subsidiaries, so that the Company itself has had to provide the money on loan, or on the security of debentures. It is hardly necessary to add that it has been quite impossible to make any profit by the sale of shareholdings in subsidiary companies. The Company publishes a list of its principal holdings. Of these, the most interesting are in the Shamva, Golden Kopje, Falcon, Bell Reef, Antelope, Asp, and Planet-Arcturus companies. The ore blocked out at the Shamva is estimated at 2,319,752 tons, averaging 21s. gold, and the others between them contain 1,703,940 tons averaging 46s. per ton. The Company also owns a large share in the Eldorado Banket company, which has paid handsome dividends, but the ore reserves are not being maintained. This holding was acquired when the assets of the Rhodesian Exploration & Development Co. were acquired.

The Shamva is one of the most notable properties developed in Rhodesia. The gold is found in a wide lode of agglomerate outcropping on the top of a hill. Five levels have been opened and the ore has been proved by numerous cross-cuts and winzes. On the first level, below the prospect level, the orebody is 920 ft. long and 110 ft. wide, averaging 4.14 dwt. gold per ton. At greater depths the dimensions in both directions decrease, though the average content is rather higher. The engineers are hopeful of an improvement in depth; but to those who are not connected with the venture the probabilities are obvious. The treatment plant is to contain 56 Nissen stamps and 10 tube-mills, and it should commence work during the next few months.

The Falcon mine is a pyritic property containing copper and gold, and the treatment of the ore will be done in the usual type of copper-smelting plant. The lodes average 40 ft. in width. Six levels have been opened, and the reserve is calculated at 178,622 tons of oxidized ore, averaging 6.4 dwt. gold per ton and 0.71% copper, and 638,389 tons of sulphide ore averaging 5.57 dwt. gold and 3.15% copper. The smelter should be ready in about a year. The Golden Kopje mine is near the Eldorado, and the milling plant of the defunct Ayrshire mine is being transported to it. Five levels have been opened, and the proved reserve consists of 210,204 tons averaging 6 dwt. per ton. The lode averages 18 ft. in width. The adjoining Union Jack mine is being developed by the Golden Kopje company, and has a reserve of 86,000 tons averaging 13 dwt. per ton. The other mines named are in an advanced state of development, and treatment plants are either ordered or under consideration. Some of the older properties in which the Company is interested have fallen on evil days. The Thistle-Etna mines have been exhausted without ever a dividend being paid, and the present developments at the Selukwe Columbia are disappointing. On the other hand, the Gaika, which after a hard struggle managed to pay two small dividends, seems to be now in a more favorable position. It will be seen from the above notes

that the Company has wide interests in mines that promise to be producers. None of them can be said to be bonanzas, and the margin of profit will be small. The total capitalization is far greater than the profit in sight.

TORONTO, CANADA

CANADIAN NICKEL CORPORATION ABSORBS THE DOMINION NICKEL CO.—MINE DEVELOPMENT AND PROPOSED PLANT.

The Canadian Nickel Corporation, Ltd., is the name of the new company which has taken over the holdings of the Dominion Nickel Co. in the Sudbury district. The capital consists of \$10,000,000 6% debenture stock and \$20,000,000 common stock, all issued. The debenture stock is redeemable at \$100, by means of an annual sinking fund, payable out of earnings, which will enable the entire issue to be redeemed in 12 years. Provision for the interest on debentures and the appropriation for the sinking fund must be made before any dividends can be declared on the common stock. The Company's property comprises several well known groups, the best of which is the old Murray mine, which was first operated by the Vivians in 1888. The Company's engineers estimate that up to May 1 development and prospecting work is estimated to have developed 6,800,000 tons of ore. The greater

CANANEA, MEXICO

PROGRESS AT THE CAPOTE SHAFT, WHERE AN ELECTRIC HOIST IS TO BE INSTALLED.—SMELTER WORK.—EXPORTS FROM SONORA DURING JULY.—TAJITOS AND LA PAZ MINES.

The new Capote shaft of the Cananea Consolidated Copper Co. will soon be completed down to the 1000-ft. level; in fact, it is already in use as far as the 900-ft. level, and is being raised from the 1000 to the 900-ft. level at present. This work is to be completed during the coming week. A new electric hoist is to be installed and will be of a similar pattern to that at the Duluth mine, as described in the *Mining and Scientific Press* of May 10 by H. L. Gooding and T. T. Read. A small temporary hoist is now used. The concrete foundation for the new hoist is being laid. The mine is being operated with three shifts, the only property of the Company being worked with anything near a full force. The Capote orebody has proved to be the largest in the district, and extends from near the surface to the 1000-ft. level. The old Chivatera dump is being shipped to the smelter, and yields about 3% copper and 12 oz. silver per ton. Between three and four carloads of the ore is being shipped direct to the smelter daily. The output of the Company for July was approximately 6,000,000 lb. of blister copper, gross, the largest in

375-H.P. HOIST WITH POSITIVE ELECTRIC BRAKE AT CANANEA-DULUTH MINE.

portion of this ore has been proved by diamond-drilling and is not yet available for stoping. There are 12 diamond-drills testing the property at various points, six of which are at the Murray mine, where it is reported that 1,000,000 tons per month is being developed. The Company has strong backing, and among the sponsors are F. S. Pearson, president of the Brazilian Traction, Power & Light Co.; J. F. Taylor, of the Lake Superior Corporation; J. E. McAllister, B. B. Lawrence, E. R. Wood, Walter Gow, and Miller Lash. The majority of these men are heavily interested in Mexican and South American traction, light, and power companies. A plant will be installed which will have a capacity of 540,000 tons per year, from which an average of 30 lb. of nickel, 12 lb. of copper, and \$1 in precious metals will be recovered at a cost of \$6.60 per ton.

The Canadian Copper Co., at the present time, is treating about 45,000 tons of ore per month, the greater portion of which comes from the Creighton mine. No. 3 mine is being developed as rapidly as possible, and on this property the Company has an enormous tonnage, a large portion of which it expects to be able to smelt direct without roasting. The plant is being enlarged, and the mines are being developed with the idea of mining 1,000,000 tons per year.

Ores sampled at the Hurricanaw district, in the north, returned tellurium 31.64%, silver 40.60%, and gold 24.80%, a true telluride of silver.

some months. No. 1 reverberatory furnace is closed at present, as it is being relined, and No. 2 was down for a short time, due to a cave-in of the lining.

Shipments through the 'port' of Agua Prieta from mines in northeastern Sonora showed quite a gain over June, and in fact was a record. It is figured that the ores and bullion exported during the month was valued at \$3,167,200, while in June the total was \$2,052,000. A number of properties have resumed shipping, while new ones have joined the ranks of producers during the month, among those being the following: El Gallo, Rivera, Matilda, Archipelago, Monte Cristo, Batuc, La Sonora, Vaquero, San Francisco, Estrella, and Santa Margerite. El Tigre shipped 63 bars of silver bullion during the month, weighing 9475 lb., and 10 cars of ore. The Moctezuma Copper Co. shipped 330 cars of ore and concentrate, while the Churunilbabi Leasing Co. shipped 10 cars.

A large body of free-milling gold ore has been opened at the Tajitos property, situated in the vicinity of Carbo. There is a large force of men employed at present, and the ore mined averages $\frac{1}{2}$ oz. gold per ton. The automobile road from its property to the Gulf of California is soon to be commenced by the West Coast Smelting & Refining Co. Grading for the new smelter will also soon be started. A group of Douglas, Arizona, men have purchased La Paz mine, situated in the Tigre district, from Jesus Urcades. A mill is to be installed as well as a power-plant.

General Mining News

ALASKA

JUNEAU

(Special Correspondence.)—Although Juneau is the oldest mining district in Alaska, and although prospecting has been going on more or less continuously and energetically since 1880, yet there are still quite extensive unexplored areas along the coast and on the islands, and during the past eight years at least, the number of prospectors has been far less than was the case 12 or 14 years ago. Indeed, many of the men who devoted all their time to prospecting up to about 1904 have since found that fishing is a much more profitable occupation, because of

DUMP AT PERSEVERANCE MINE, JUNEAU.

the many disappointments the prospectors have met with when attempting to invest capital to develop their discoveries.

Juneau, July 30.

COCHISE COUNTY

The second drill-hole being put down to tap the gas from the Holbrook shaft's old fire zone will probably enter the gas area shortly. The first drill-hole, which got the gas at about 400 ft., is continuing to bring out a large volume daily. Behind the supply-house at the Holbrook there is a raise which is also being used as an outlet for the gas. With the additional drill-holes that are to be put down, there would seem to be excellent prospects for ridding the mine of this trouble and danger permanently.

ARIZONA

PINAL COUNTY

(Special Correspondence.)—The Ray Consolidated Copper Co. produced 195,000 tons of ore in June, and there is now being mined 7000 tons of ore per day. There are 1600 men at work in the mine, and the payroll for June was \$140,000. At this rate there is being expended in wages \$1,680,000 per year. There has been no time lost in bringing the mine up to its present producing capacity. Six months ago the daily output was 5000 tons and will shortly be 8000 tons per day. The continued subsidence of Ray mountain is still noticeable, and the caved area between here and the town of Sonora has extended during the past few weeks. The surface continues to drop gradually near the M. & H. shaft, and a break has appeared on the old Ray Central hill where houses formerly stood.

Ray, July 31.

CALIFORNIA

BUTTE COUNTY

G. W. Wooley, manager of the Klondyke Gravel Mining Co., is authority for the statement that he recently uncovered at his mine here a large body of manganese ore. Samples sent to Salt Lake City gave a good result.

CALAVERAS COUNTY

(Special Correspondence.)—The Relner Mining Co., operating near Altaville, recently published a folder giving details of its properties and plant, and is offering stock for sale for further equipment. The area of ground

is 550 acres and part contains a gravel formation. On July 21, 1913, bedrock in the old river was reached. Estimates of the channel owned by the Company give 200 ft. width, $2\frac{1}{4}$ miles long, and gold-bearing gravel is about 50 ft. thick, containing probably 4,600,000 tons of gravel averaging \$2.50 to \$11 per ton, besides some rich black sand. Profits from this are estimated to be large. The 20-stamp mill was destroyed by fire on December 7, 1912, and more money is required to replace it; hence the appeal.

The other equipment is in good order, but it is said locally that there is a heavy mortgage on the plant, due immediately. A few weeks ago the property was shut down, and some of the employees have two months' pay owing them. Local opinion is that, under proper management, the property might make good; but stock operations in the East have been heavy.

Altaville, August 3.

ELDORADO COUNTY

The old Union mine, which has been idle for several years, is to be reopened. For 17 years it was a steady producer.

NEVADA COUNTY

In the damage suit of J. Cornelius v. the Brunswick Consolidated Gold Mining Co., the court found for the defendant. The Union Consolidated Mining Co., operating at Virginia City, Nevada, has purchased a controlling interest in the Blue Quartz Mining Co., of Nevada City, in this county.

PLACER COUNTY

The Plumas Bonanza mine, on Winers creek, is opened to a depth of 100 ft. on a vein of white quartz. The ore is estimated at \$8 to \$10 per ton. Ore obtained from the cross-cut will be crushed in the 3-stamp mill placed on the property last fall.

SIERRA COUNTY

(Special Correspondence.)—The shaft and lower level of the old West End mine, east of Whiskeytown, is being unwatered by Briceland Blair, Newton Eaton, and other people of Kennett, who have installed an efficient steam-hoist and pump on the property. The property was a good producer 30 years ago from the upper levels, and a short extension of a level run from the bottom of the shaft is expected to give about 100 ft. of new stoping ground. The Gambrinus mine on Whiskey creek, after a temporary idleness, due to shortage of water-power, will soon resume development work, the ditch having been repaired and water-supply increased. Development consists in the driving of a cross-cut from the lower level, 125 ft. on the branch of the main vein. Before the present shut-down, this cross-cut had been driven about 20 ft., and in another 20 ft. should cut the vein. The mine should soon be on a profitable footing, as this vein in the upper levels paid handsomely to the early operators. On July 26, John S. Strode, John W. Strode, and James Hener started the 10-stamp Straub mill which they recently erected on their Blackhawk claim on the headwaters of Mad Ox creek, above the old Mad Ox mine. They report the operation satisfactory. They spent several years prospecting and developing the property, and had a large tonnage of milling ore blocked out and on the dump before purchasing the mill. If all prospective mine operators would proceed in this practical way there would be many less idle mills in the country. Seven auto-loads of 'hoosters', including some state officials, passed through here on July 26, bound for up-country points and to look into the possibilities of a state highway passing through this district into Trinity county. This is of vital interest to mining as well as other people, as transportation is one of the most expensive features of mine operation in these counties, and there is much room for improvement in the roads.

Whiskeytown, July 27.

The Russell placer mines near Igo, bonded by Los Angeles people, are to be worked with new equipment. The Company has been mining rich gravel for several weeks with a hydraulic elevator, but recently completed a combination dredge drag-line excavator steam-shovel device.

The machine was especially designed to meet the varying requirements of the ground and is an interesting piece of machinery. Fred Grotfend has arranged for the immediate installation of a modern hoisting and pumping plant at the Donkey zinc-copper mine, near Ingot, and will sink the shaft below the present workings. The working force has been increased. Consignments of the richer ore will be shipped to Utah plants while the new development is in progress. Later on activities will be resumed at the Baker.

SISKIYOU COUNTY

The new company recently acquiring the new coal deposits near Ager from the Yreka Development Co. has two diamond-drills at work, exploring the coal seams. Michigan people have acquired the Blue Ledge copper mines on the upper Applegate river. About two miles of development has been done, and high-grade ore opened. Transport difficulties have handicapped the district so far, but it is proposed to build a railroad from the field to Medford or some town in Oregon.

TRINITY COUNTY

(Special Correspondence.)—Robert McIlwaine and Chas. Kingsberg have leased the Blue Jay for another year and will begin active operation about the latter part of August. The Dorleska, situated near the head of Coffee creek, has recently been examined for an English corporation, and it is likely that this good property will again take its place among the producers of Trinity county. The Sikes Mining Co. has discontinued work on the 'Poverty Slide' at Trinity Center owing to lack of water to operate the giants. A few men are still at work cleaning the flumes.

MAP OF TRINITY COUNTY.

The body of oxidized ore at the Headlight mine has been worked out, and the mill is closed pending the development of a process to treat the large body of sulphide ore underlying the gossan. This ore carries about 47% sulphides, including 3 to 4% copper. The ore cannot be roasted, owing to Government forestry restrictions, but a wet process is giving good results on small tests, and it is probable that this property will be producing again in the early part of next year. The 13-cu. ft. dredge of the Alta Bert Gold Dredging Co. has been in continuous operation since it was completed last February. The Company owns 600 acres along the Trinity river, at Trinity Center, and is turning over about two acres of ground per month. A 60-ft. steel spud, weighing 72 tons, is being assembled on the ground, and will be installed within the next few weeks. To the present time a headline has been used to hold the dredge up to the working face. A company has bonded the Carr ranch, at Carrville, and a drill is at work prospecting the ground.

Trinity Center, July 5.

TUOLUMNE COUNTY

(Special Correspondence.)—Gold-bearing gravel was opened this week in the Humbung mine, at Table mountain, and it is the belief that the ancient river channel has at last been uncovered. The company has been carrying on development for several years, during which an adit was driven into the lava-capped mountain almost 1000 ft. The work has been done under the direction of J. L. Witney.

The Gross mine, at Tuttle town, has been bonded to George Weston, Percy E. Weston, and A. J. Dutton, of Salt Lake City, and active work will begin at the property during the coming week. According to the terms of the agreement, permission to stope ore is given only on condition that the shaft first be sunk an additional 100 ft. Large orebodies have been developed by former operators, and it is said that a mill much larger than the one now on the property will probably be installed when the sinking specified in the bond is completed.

The San Francisco company which is preparing to mine the bed of the Tuolumne river at Kanaka bar, one mile above Jacksonville, expects to begin operations by August 15 with a crew of 12 to 15 men, Henry Keith in charge. A wing-dam 180 ft. long has been constructed to divert the stream and expose the channel several hundred feet, and a 'China' pump, now being installed, will handle the seepage. An elevator will be used to convey the gravel to the sluice for washing. The gravel deposit is several hundred feet wide and varies in depth up to 25 feet.

The first clean-up since the resumption of operations at the Atlas, near Tuttle town, was made last week, and is most satisfactory to the management. B. C. Haywards, interested in the Santa Ysabel mine, at Stent, is reported as saying, while on a visit to the property last week, that operations would likely be resumed in the near future. Howard Pollion, of New York, this week secured an option on a portion of the Carlin property, between Jamestown and the Harvard mine, and will at once begin development work. The property will be explored by means of an adit. The Clark Development Co., a new corporation having a capital stock of \$10,000, with shares at \$1 each, will shortly begin the development of the Clark ranch mine, situated near the Hazel Dell. The Company's principal place of business is Sonora, and the directors are H. F. Clark, of Sonlsbyville, A. Y. Werner, of Carson City, Nevada, and Rowan Hardin, of Sonora.

Sonora, August 2.

YUBA COUNTY

During the six months ended June 30, the Natomas Consolidated of California reports a gross income of \$1,272,626, operating expenses \$622,433, mortgage interest \$416,937, leaving a profit of \$233,256. The June earnings were \$240,878, with a profit of \$66,278. No. 5 gold-dredge of the Natomas Consolidated, situated about a mile from Hammonton, capsized on July 31, owing to the breaking of one of the guy lines. The loss may be heavy, as the dredge may have to be entirely dismantled before being righted.

COLORADO

CLEAR CREEK COUNTY

(Special Correspondence.)—James Teeters, operating the Gold and Silver property on Ute creek, has opened an 8-in. streak of solid ore which assays 1316 oz. silver, 5.24 oz. gold, and 30% lead. The find was made at the bottom of the 70-ft. shaft. The Idaho-Bride company, operating the Seaton mine, is shipping to the Argo mill \$3.50 ore, a net profit of 50c. per ton being received in settlement. E. D. Payne is manager. A shoot 2 ft. wide and worth 40 oz. gold and 186 oz. silver per ton has been opened on the 800-ft. level of the Little Mattie mine. The discovery was made 200 ft. west of the shaft. Shipments have been started. W. L. Leebrick is manager. Work has been resumed on the Katie Emmett mine on Chicago mountain. The 10-stamp mill is crushing dump ore. W. W. Cannady is manager. The old United States mill, on lower Fall river, has been leased to Bartlow & Mason. The machinery is being overhauled and ore treatment will be started in a few days. Work has been resumed at the Keystone

mine, situated on Bellevue mountain. Stoping is in progress on an orebody which is from 3 to 6 ft. wide and assays \$14 per ton. The product is consigned to a zinc plant at Denver. N. C. Brauch is the owner. An orebody from 8 to 10 ft. wide has been opened at the bottom of the 120-ft. winze sunk from the Two Brothers adit on the Specie vein. It is worth \$16 per ton in gold and silver. On the hanging wall an 8-in. streak of smelting ore is exposed that mills \$85 per ton. John Owen is manager. Shipments have been started from the Bald Eagle mine on Seaton mountain, the product being consigned to the Combination mill. H. T. Rogers is manager. It is stated that the 150-ton mill at the Oneida mine, at Freeland, will be completed during the next 30 days. The building is finished and the machinery ordered. This plant will be equipped for concentration, amalgamation, and an electrolytic process. John Owen is lessee. Heavy shipments are going out from the Golden Edge mine, the ore being of milling grade. J. P. Ruth is operating under lease.

Idaho Springs, August 2.

GILPIN COUNTY

New equipment is to be added to the Castle Rock mine, in Chase gulch, and machine drills are to take the place of hand work in the mine. The main shaft is 416 ft. deep, and the 300-ft. level cross-cut was driven north 100 ft., cutting ore, and a winze 60 ft. deep has produced 22½ cords (200 tons), which was treated at the Polar Star mill, at Black Hawk, yielding 48 oz. retorted gold. The tailing is worth \$10 per ton. Joseph Tuckfield is mine manager. Klein & Co. has taken a lease on the Sterling property on Bates hill.

The 'pool' working the Alps mine, on Quartz hill, is keeping a battery working at the Polar Star mill, on ore from the 800-ft. level. A streak in the vein is yielding smelting ore. Lessees at the Corydon are doing well. The 10-stamp mill of the Gilpin-Eureka company is working two shifts. The Barnes mine, on Quartz hill, is being dewatered below the Quartz Hill adit-level.

TELLER COUNTY (CRIPPLE CREEK)

According to local statistics, the July output of the district was as follows:

Plant.	Tonnage.	Av. val.	Total val.
Golden Cycle	32,000	\$20.00	\$ 640,000
Portland (Colorado City)....	9,665	22.00	212,630
Smelters	3,825	65.00	248,625
Portland (Cripple Creek)....	13,600	2.60	35,360
Stratton's Independence	11,073	2.23	24,693
Colburn-Ajax	4,400	2.84	12,496
Kavanagh-Jo Dandy	1,700	2.20	3,740
Gaylord-Dante	1,600	2.50	4,000
Rex M. & M. Co.....	1,200	1.10	1,320
Wild Horse	1,100	2.20	2,420
Isabella	700	2.00	1,400
Total	80,863		\$1,186,684

Owing to the Fourth of July holidays the yield shows a small decrease on that of June. Dividends paid were as follows: Portland Gold Mining Co., 2c. per share, \$60,000; Vindicator Con. G. M. Co., 3c. per share, \$45,000; Golden Cycle Mining Co., 2c. per share, \$30,000; and Mary McKinney Mining Co., 2c. per share, \$26,185; a total of \$161,185.

The Homestake mill, on Ironclad hill, owned and operated by Thomas Kavanagh, will be operated as a custom low-grade plant some time in August, when ore in 100-ton lots will be accepted. The ore will be purchased outright, a charge of \$3 being made for treatment, which will be the minimum. The ore must be delivered to the mill. Before one lot can be started through the mill, the ore before it must be cleaned up.

IDAHO

SHOSHONE COUNTY

(Special Correspondence.)—Placer mining is active in the Murray section of the Coeur d'Alene, the late rains and heavy snows of last winter giving ample water-supply for extensive operations. One of the largest crews at work

is on East Slagle creek, where Dunlap & Smith, pioneer placer miners, are handling a large strip of rich 'pay-dirt.' Ten miners are employed in the work, the booming method being employed in getting to bedrock, which ranges from 8 to 12 ft. in depth. Assured of a good water-supply, the owners are working a larger strip this summer than for many seasons, and from present outlook will make one of the largest clean-ups of the north side. The gold is coarse and averages \$18 per ounce. Nuggets running from \$25 to \$55 have been taken from the creek, but most of the nuggets average from \$1 to \$5 each. The season's clean-up in this district will probably run close to \$10,000, it is stated at Wardner. The work is under the management of Archie Smith, one of the early settlers in the Murray district and one of the best placer workers operating in the Coeur d'Alene.

Spokane, July 30.

The Snowstorm Mining Co., operating at Larson, reports the following during the year ended June 30, 1913: Men employed, 130; development below No. 1 adit, shaft-sinking and winze; ore milled and concentrate shipped, 99,545 tons; operating profit, \$228,563; dividends, \$142,452.

Property valuations fixed by the County Commissioners are as follows: Coeur d'Alene Development Co., concentrate increased from \$22,500 to \$24,800; Gold Hunter Mining & Smelting Co., concentrate from \$45,000 to \$49,000, compressor from \$8000 to \$8700; Success Mining Co., mill from \$25,000 to \$30,000. Decreases were: Hecla Mining Co., mill from \$22,000 to \$17,000, machinery from \$52,935 to \$49,800; Bunker Hill & Sullivan Mining & Concentrating Co., mill from \$350,000 to \$250,000, and power-plant from \$100,000 to \$89,000; and Hercules Mining Co., mill \$125,000 to \$105,000, and machinery \$32,215 to \$28,000.

MICHIGAN

HOUGHTON COUNTY

The miners' strike still continues, but the present labor disturbance is countenanced by about 15% of the employees of the various operating companies; certainly not over 20%, and probably less than this number on the Calumet & Hecla and subsidiaries. It is being made at a time when the mines are paying the highest wages in the history of copper-mining in this district. Trammers receive from \$2.60 to \$3.16 per shift, while the average wage paid to miners is \$3.50. The Western Federation of Miners denies the above statement made by the companies. Work has been resumed at several of the mines in pumping and underground work. There have been several slight disturbances, but there is a feeling among the men against the strike. The companies will not recognize the Federation.

MONTANA

MISSOULA COUNTY

(Special Correspondence.)—The East Butte company is maintaining a production of about 2,225,000 lb. of copper per month in spite of the improvements being made to the smelter. These will be completed in about another month, and then the Company will be in a position to increase the production, if necessary, by at least 500,000 lb. per month. Development is being vigorously conducted, and the ore reserves are considerably larger today than at any time in the history of the property. The East Butte ought to be paying dividends early next year. The North Butte company has passed the 2500-ft. point in the sinking of the Granite Mountain shaft, and at the present rate of progress it is estimated that a depth of 2800 ft. will be reached by the middle of October. Then a sump will be sunk and connection made with the 2800-ft. level of the Speculator shaft. It has not yet been determined when the Speculator shaft will be closed for retimbering, and all the ore hoisted through the Granite Mountain shaft, but it is believed that so long as the Speculator shaft remains in a perfectly safe condition it will be operated.

Butte, July 26.

The King and Queen mine is situated near Keystone, in the Spring Gulch district, and over 5000 ft. of development has been done to date. The present mill product

comes from an intermediate cross-cut adit driven to the vein, and from the mouth of this, ore is delivered by gravity tramway to a track-level above the mill crusher. An adit from this point is in 1800 ft., and should cut the vein a 100 ft. farther. This will be the main working level. The vein at present is 15 ft. wide over a length of 300 to 350 ft. The ore is similar to the galena product of the Coeur d'Alene mines. The mill is of 75-ton capacity, consisting of a crusher, rolls, jigs, and tables. Concentrate is shipped over the Milwaukee railroad. Water is fairly scarce, and direct means of transport is necessary. John F. Hinckley is in charge, and Pittsburgh people are interested.

The quarterly report of the North Butte Mining Co. for the term ended June 30, shows that development covered 4769 ft. The continued development of the Edith May and Adirondack veins on the 2400 and 2600-ft. levels, together with the continued eastward development of ore in the Snowball vein on the 2000 and 2200-ft. levels, has more than replaced the ore which has been mined during the quarter. The Edith May shows from 4 to 7 ft. of 4 to 5% copper and 1.3 to 2 oz. silver per ton; the Adirondack shows 4 to 10 ft. of 3 to 5% copper and 1.5 to 2.25 oz. silver; and the Snowball shows from 4 to 5 ft. of 3 to 8% copper and 5.5 to 8 oz. silver ore over good lengths opened.

NEVADA

CLARK COUNTY

(Special Correspondence.)—Work by lessees in the Quartette property is as follows: The original Holmes lease, on the 100-ft. level east of the Crocker shaft, is producing 40 tons of \$12 ore per day. About 5000 tons of ore is opened in this lease. The Post lease is shipping 20 tons of \$15 ore per day from the 140-ft. level. Holmes and Mc-

GENERAL VIEW OF QUARTETTE PROPERTY AND DISTRICT.

Clelland, operating the No. 3 lease on the 200-ft. level east of the Crocker shaft, are breaking down 18 in. of \$40 ore. On the 600-ft. level, east of the main shaft, Pemberton and Jonas are taking out about 30 tons per day. The ore-shoot has been developed for a distance of 85 ft. to date, disclosing 10 ft. of ore assaying about \$35, with 15 in. on the hanging wall yielding about \$200 per ton. At the present time there are 55 men employed on the property in the mine, mill, and cyanide plant. The 40-stamp mill is running three shifts, but on account of the overhauling of the mill, only 20 stamps are available until new parts now ordered have arrived. Costs are: mining, including development, \$2.37; milling, \$1.01; and cyaniding, \$1.65 per ton.

Searchlight, July 26.

ELKO COUNTY

(Special Correspondence.)—There is a fair amount of activity at Tennessee Gulch, 15 to 20 miles west of Jarbidge, which was first prospected about sixteen years ago. Work is to be resumed at the Gold Bug and Oro Fino mines by Theodore Parks and associates. In the former property there are a number of veins, and one has been opened to 185 ft., showing rich ore. A 3-stamp mill is on the ground and crushed some ore. A vein in the Oro Fino, three miles from the Gold Bug, can be traced for 3000 ft., and 10 ft. of ore has been opened at one point. A group of claims at Martin Gulch, four miles distant, is opening silver-lead ore.

Jarbidge, August 1.

The South Nevada Gold Mining Co. is erecting a good

deal of equipment and houses at its property, six miles east of Las Vegas. The mine has been opened on four levels, and two Beers type roller mills will crush 100 tons per day.

ESMERALDA COUNTY

The Goldfield Consolidated Mines Co. reports the following results for the quarter ended June 30:

Ore treated, tons	87,718
Gold production	\$1,187,345
Costs	593,763

Profit\$ 593,582

The Goldfield Oro shaft is being sunk by two shifts, using machine-drills in the dacite rock. The Silver Pick shaft is down 400 ft. in dacite, and the station at 513 ft. is being cut in the Booth shaft in a contact of alaskite and shale.

EUREKA COUNTY

An important ore discovery has recently been made below the big fault in the Buckhorn. The find was made in the long haulage level below any ore known up to that time. It shows 28 ft. of ore assaying about \$20 per ton, but no development work has been done on it outside of cross-cutting it with the level, and none is likely to be done until the milling plant is completed. Work on the new mill is progressing well, and there is only 9 miles of electric transmission line to complete. Heavy rain has interfered with haulage of supplies.

The option on 41 claims at Prospect mountain, including the old Dunderberg mine, by Samuel Newhouse and associates, was given in our last week's issue as being in Juab county, Utah, instead of Eureka, Nevada.

HUMBOLDT COUNTY

The Charleston National mine, at National, is employing 15 men, and another shift is to be started soon. The shaft is 250 ft. deep, and at 300 ft. a cross-cut will be driven to the vein. The National Mines Co. has opened high-grade ore within 150 ft. of the Charleston end-line.

The Kennedy mining district, situated 55 miles south of Winnemucca on the Southern Pacific railway, has been described in an interesting paper by Paul Klopstock, in the *Transactions* of the A. I. M. E. In 1893, C. E. Kennedy first opened a rich vein, and shipped ore to the Utah smelters. The district is embraced practically in a belt of eruptive rocks which begins to the south of Gold Note mountain, and then runs north for a distance of 2½ miles to Water cañon, where the porphyries are capped by a flow of basalt. Beyond Water cañon no extensive evidence of mineralization is evident. Quartz-porphyrries, grano-diorite, gneiss, and diabase are mostly associated with the ore-bearing veins, while the southern portion of Gold Note mountain is chiefly composed of andesite. At the surface, and to depths ranging from 50 to 125 ft. on the dip of the veins, the ores are entirely oxidized; the following analysis is submitted as representative of these ores: Insoluble, 75%; iron, from 9 to 15%; and sulphur, 3%; Au, 0.75%; and Ag, 12 oz. The assays range from \$8 to \$200 per ton, but average \$14 per ton. At the bottom of this ore a secondary sulphide ore is found, and ore from 50 to 75 ft. deep, assaying iron 30% and sulphur 25%, after which the primary sulphides are encountered. These contain 33.5% iron and 14% sulphur.

The Imperial mill consists of 20 stamps, sand leaching and slime decantation plants using cyanide, and is to be increased to 125-ton capacity. Tests on the sulphide ore show that fine grinding is necessary, while agitators and a filter-press are to be installed.

LYON COUNTY

At the Casting Copper mine of the Nevada-Douglas, the 40-ft. level is in 5 to 6 ft. of 6% copper ore, while on the 100-ft. level the cross-cut has opened 16 ft. of 5% ore. Shipments from this property average 5% copper. The middle-level drift on the Maybe shoot in the Douglas Hill has gone through 25 ft. of ore before reaching the east limit. Ore averages 4 per cent.

On the 800-ft. level of the Ludwig mine, driving is being pushed steadily south in the hanging wall country. This material is at present heavily mineralized with iron pyrite

and a small amount of chalcopryrite. On the 750-ft. level, work of blocking out the ore is still being carried on. The body was cut upon its north extremity, and is extending southward in the workings now being pushed. The ore averages 10% copper.

During the week ended July 25 the Thompson smelter received 4198 tons of ore, of which 1126 tons was from the Nevada-Douglas and 2026 tons from the Mason Valley. There were four cars of matte shipped.

MINERAL COUNTY

There are now 131 men on the payrolls at Rawhide, more than at any time in the history of that 'camp,' not excluding the 'boom' period of five years ago. The Nevada New Mines Co. is owner of nearly 200 acres of ground, from which lessees have taken over \$50,000 worth of gold ore from surface or shallow workings, and in which ore-bodies are developed for 500 ft. in depth and for nearly 600 ft. in length. The Company is the owner of a milling plant that has cost over \$70,000, and the plant is in full operation and producing enough bullion to make the Company self-sustaining while carrying on development, which is adding to the reserves right along.

The Cinnabar King quicksilver mine, at Cinnabar, 11 miles east of Mina, is showing 5½ ft. of high-grade ore, and an option for \$60,000 has been given to Eastern capitalists. The West Extension group is under option to Los Angeles people for \$40,000.

WHITE PINE COUNTY

For some time past the Nevada Consolidated Copper Co. has been experimenting with the oil-flotation process on porphyry ores at McGill. It is understood that the laboratory experiments have been highly satisfactory; in fact, beyond expectations. The tests were made on a small scale, but have been of sufficient magnitude to demonstrate that the ores of the Ely district are susceptible to treatment by this new process, and therefore ground is now being broken for the erection of a testing plant with a capacity of 100 tons per day. The slime from the mill contains about 25% of the copper content of the ore, and flotation will be tried on this product.

OREGON

BAKER COUNTY

In No. 3 adit of the old Cougar mine, in the Granite district, ore worth \$12 was recently opened, and on driving 300 ft. the shoot was proved to be 300 ft. long, 4 ft. wide, and assaying up to \$90 per ton. The property is equipped with a stamp-mill and cyanide plant and is owned by Spokane people.

JACKSON COUNTY

(Special Correspondence.)—The old Whitney mine, on the east side of Gold hill, is being reopened by Humphrey & Son, of Bellingham, Washington, who have it under lease. Years ago it produced a great deal of gold from its rich deposits of free-milling ore. Legal entanglements were responsible for its closing down and years of idleness. Now all points in dispute have been settled, and the new management has set to work to retimber, overhaul, and set it going again. The Braden is another Gold Hill property which is being opened. Under Mr. Horn, the manager, a new adit is being driven on a lower level to cut the main orebody, lost by a cave-in of the old workings. A new and rich discovery was made during the past week on the Lucky Bart mine, at Sardine creek, near Gold hill. A 3-ft. vein was found that is averaging \$40 per ton in the mill. R. Bordier, of Paris, France, secretary of the French company that owns and operates the Bill Nye mine in the Gold Hill district, is inspecting the property. With the local manager of the mine, F. C. Bellamy, Mr. Bordier is planning better equipment and deeper development. The mine is equipped with a 10-stamp mill and has been one of the leading producers of the district. A deal was completed last week by which the Blue Ledge copper mine, in the upper Applegate district, and on the Oregon-California divide, was sold by Robert S. Towne and associates to a company of Michigan

people, among the latter being H. C. Russell, of Marquette. Philomath, July 15.

UTAH

JUAN COUNTY

The Emerald Mining Co. has filed suit against the Centennial Eureka Mining Co. for alleged wrongful extraction of 2000 tons of ore from its Emerald lode claim in the Tintic district. Damages are assessed at \$100,000.

SALT LAKE COUNTY

Fire said to have been caused by lightning resulted in the destruction on August 3 of the transformer and compressor plant of the Utah Copper Co. at Bingham. The plant was practically new, and the loss is estimated at \$100,000.

SUMMIT COUNTY

The Snake Creek tunnel is in over 6000 ft., and during 26 days in July it was driven 300 ft., and 400 ft. is expected during a full run.

The last installment, \$485,000, of the judgment held against the Silver King Coalition Mines Co., in the Silver King Consolidated Mining Co.'s suit, was paid on August 1, thus concluding the case. There is some dispute over the fees to be paid the lawyers by the Consolidated company, they asking \$100,000; but this will be settled by the court.

WASHINGTON

FERRY COUNTY

The Granby company, of British Columbia, has taken an option on the Lame Foot group of mines, near Curlew lake, in this county, for \$150,000, from 'Dutch Jake' Goetz and Harry Baer. The group, comprising 15 claims, is 8 miles north of Republic; the Granby company already has a diamond-drill at work. The contract stipulates that not less than \$25,000 shall be expended in prospecting the deposits, principally an iron fluxing ore, within 18 months from May 1, 1912.

CANADA

BRITISH COLUMBIA

During the three months ended June 30, the Standard Silver-Lead Mining Co. made net earnings of \$195,667, while the surplus is \$234,601.

ONTARIO

During the week ended August 2, members of the International Geological Congress visited Cobalt, where various tours of inspection were made, and interesting papers read on work in the district.

During June the Buffalo Mines, Ltd., operations resulted as follows:

Ore treated, tons	5955
Average assay of ore, ounces	31.15
Silver recovered, ounces	161,331
Silver paid for during month (shipped previously), ounces	33,621

No estimates are made of high-grade ore, but returns are included under 'ounces of silver paid for' as smelters make settlement.

MEXICO

CHIHUAHUA

It is estimated that 7000 refugees from different parts of the state arrived at Chihuahua during June. The present population of the city is estimated at 47,000 as a result. This influx is due chiefly to the activities of rebels now all through the state.

JALISCO

A great deal of the structural iron for the framework of the reduction plant of the Cinco Minas Co. in the Hostotl-paquillo district has reached the property, and the work of erecting it has been commenced.

Two American mining camps in the Parnaso district of Jalisco, those of the Boca Ancha Mining Co., a Chicago concern, and the Gold Standard Mining Co., in which Philadelphia men are interested, have been held up by bandits under the leadership of Celso de Santiago. After looting they set fire to the buildings. Those of the Gold Standard company were entirely destroyed, according to reports.

Schools and Societies

The new officers of the CHEMICAL, METALLURGICAL AND MINING SOCIETY OF SOUTH AFRICA are as follows: president, Alex. Richardson; vice-presidents, G. H. Stanley, H. A. White, and J. E. Thomas; honorable treasurer, J. Littlejohn; members of council, K. L. Graham, J. A. Wilkinson, J. Gray, F. W. Watson, C. Toombs, T. Donaldson, A. Whitby, A. Salkinson, E. Pam, F. Wartenweiler, John Watson, and H. Meyer.

The annual meeting of the AMERICAN MINE SAFETY ASSOCIATION, composed of leading coal and metal-mine operators, mining engineers, mine-safety engineers, and mine surgeons, will be held at Pittsburgh, September 22 to 24. This Association, which held its first meeting a year ago, has for its purpose a reduction of the number of accidents in the mines and quarries (3602 in the year 1911) and the alleviation of the more than 60,000 men who are injured each year.

The IMPERIAL TOKYO UNIVERSITY, Japan, held its annual commencement on July 11. There were 954 graduates, namely: law, 391; medicine, 141; engineering, 188; literature, 86; science, 31; and agriculture, 117. The distinguished visitors were shown the university collection of historical documents and scientific specimens. Among them were ancient art objects of Korea, maps and documents illustrating the communications between ancient Japan and Annam, and scientific apparatus showing radium emanation.

The AMERICAN MINING CONGRESS will hold its convention and mining exposition at Philadelphia, during the week of October 20. The two-fold attraction of the convention and exposition gives every indication that it will be one of the greatest meetings of mining men in the history of this country. The plans have gone far enough to satisfy the officers of the Congress that the industrial show will be a success, and promises from members and other mining men leave no doubt as to the outcome of the convention. Manufacturers of mining machinery, rescue and first-aid apparatus, and safety appliances are to be given an opportunity to display their apparatus before the mining men of the country at this industrial exposition. J. F. Callbreath is secretary at the permanent headquarters, Majestic building, Denver, Colorado.

Among the fifty papers to be read at the Butte meeting of the AMERICAN INSTITUTE OF MINING ENGINEERS from August 16 to 21 are the following: 'The Ore Deposits at Butte, Montana,' by Reno H. Sales; 'Mineral Associations at Butte,' by Darsie C. Bard and M. H. Gidel; 'Applied Geology in the Butte District,' by F. A. Linforth; 'Timbering in the Butte Mines,' by B. H. Dunshee; 'Shaft-Sinking Methods at Butte,' by Norman Braly; 'Development of the Basic-Lined Converter for Copper Mattes,' by E. P. Mathewson; 'Great Falls Converter Practice,' by A. E. Wheeler and M. W. Krejci; 'The Development of Blast-Furnace Construction at the Boston & Montana Smelter,' by John A. Church, Jr.; 'Thermal Effects of Blast Furnace Jackets,' by Robert P. Roberts; 'Increasing the Efficiency of McDougall Roasters at the Great Falls Smelter of the Anaconda Copper Mining Company,' by F. R. Corwin and S. S. Rogers; 'The Great Falls Flue System and Chimney,' by C. W. Goodale and J. H. Klepinger; 'Determination of Gases in Smelter Flues; and Notes on the Determination of Dust Losses at the Washoe Reduction Works,' by Edgar M. Dunn; 'Arsenic Trioxide from Flue Dust,' by James O. Elton; 'The Determination of Arsenic and Antimony in Converter and Electrolytic Copper,' by E. E. Brownson; 'Notes on the Great Falls Electrolytic Plant,' by W. T. Burns; 'The Distribution of Precious Metals in Converter Copper, and the Relation Between the Precious Metals and Arsenic and Antimony,' by A. E. Wheeler; 'The Great Falls System of Concentration Installed in Section No. 1, Washoe Concentrator, Anaconda,' by Albert E. Wiggin; 'Concentration of Slimes at Anaconda, Montana,' by Ralph Hayden; 'Application of Hindered Settling to Hydraulic Classifiers,' by E. S. Bardwell; and 'The Anaconda Classifier,' by Robert Ammon.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

H. F. FOX is in Michigan on a visit.
C. C. BROADWATER has gone to London.
JOHN D. RYAN has returned from Europe.
JOHN ROOKE-COWELL was in Boston recently.
JOHN B. FARISH was in New York City recently.
R. B. LAMB was at Cobalt during the week ended July 27.
C. S. HERZIG was in New York and has gone to Oklahoma.
A. E. BORIE has returned to New York from a holiday trip.
A. H. BURROUGHS, Jr., has left New York City for Nome, Alaska.
CHARLES JANIN was in London recently and has returned to Geneva.
L. D. RICKETTS has returned to New York from the southwestern states.
W. H. STORMS is in Tuolumne county, California, on a professional visit.
E. M. HAMILTON has gone to Salvador, where he will be for several months.
C. W. MERRILL has returned to San Francisco from his vacation at Lake Tahoe.
KIRBY THOMAS has been visiting Sudbury and Cobalt, and has returned to New York.
WILLIAM H. RADFORD, of San Francisco, went to Arizona on August 2 on professional work.
H. WHITTINGHAM, who has been assisting George H. Garrey on mine examination work in Mexico, has returned to El Paso.
JOSEPH MACDONALD, formerly of the Alaska Treadwell Mining Co., has been acquitted of the charge against him at Juneau, Alaska.
J. ALLEN VEATCH has returned to Napa, California, from Panama, where he has been for the past eight months investigating the oil resources of the isthmus.
GEORGE H. GARREY is in the state of Coahuila, Mexico, making a geological examination of a number of mines for the American Smelting & Refining Company.
FELIX McDONALD, mine superintendent of the Ohio Copper Co., Utah, has resigned to take a similar position with the Inspiration Consolidated Copper Co., Arizona.

Obituary

ALFONSO A. TREGIDGO, well known among miners in Nevada county, and once president of the State Miners' Association, died at San Francisco on August 1.

FERGUSON DOAK, manager of the American Smelting & Refining Co.'s agency in the Parral district, and one of the best known mining men in northern Mexico, died on June 8 from a stroke of apoplexy.

JOHN MILNE, best known as a seismologist, but whose earlier work was in geology and mining engineering, died July 31 at his home, Shide House Hill, in the Isle of Wight, at the age of 63. He was born in Liverpool in 1850 and after graduating from Kings College and the Royal School of Mines, he engaged in mining work in Newfoundland, in the employ of Sir James Anderson, Cyrus Field, and others. Later he served as the geologist of an expedition into northwestern Arabia. In Japan, where he spent twenty years in the establishment of nearly 1000 government stations for the observation and study of earthquake phenomena, he married Tone Noritsune, daughter of the abbot of Ganjo-ji, in Hakodate. His work in Japan has served to make that country the leader in the recording and study of earthquakes. Returning to England in his later years, he organized a seismic survey of the world for the British Association for the advancement of Science, and in this connection traveled extensively in Russia, Siberia, Mongolia, China, the Kurile islands, Korea, the Philippines, Borneo, Australasia, and the United States. Ripe in years and rich in honors, he goes to his long home lamented by many friends the world around.

The Metal Markets

LOCAL METAL PRICES

San Francisco, August 7.

Antimony.....	12-12½c	Quicksilver (flask).....	\$41
Electrolytic Copper.....	16-16½c	Tin.....	46-47½c
Pig Lead.....	4.75-5.70c	Spelter.....	7-7½c
Zinc dust, 1400 lb. casks, per 100 lb., small lots \$9.50-9.75; large \$7.50-8.50			

EASTERN METAL MARKETS

(By wire from New York.)

NEW YORK, August 6.—Metal market is showing an improvement generally. Copper continues strong with considerable September copper still to be purchased. A general improvement in copper stocks is to be noted, in which the Lake Superior stocks have also participated, regardless of the strike in that district. An advance of ¼c. in copper is announced. Little metal is on hand for immediate delivery. London market is reported steady. Copper opened at 68 5s. The Amalgamated and American Smelting agencies in London quote £71 10s. for September and £71 15s. for October delivery. Lead market firm and spelter strong. The Granby dividend is \$1.50 for last year.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

May	60.88	60.21	Nov.	62.73
June	61.29	59.03	Dec.	63.38

Silver prices have been well maintained, according to Samuel Montagu & Co., on July 17, although the undertone of the market cannot be considered as strong, for rates have been controlled by the very small size of the amounts offering from the usual channels of supply. At advancing prices, however, there is a disposition to sell with some freedom, and for that reason, much higher prices appear unlikely. Buying has been confined chiefly to the covering of sale contracts as they fall due. Indian purchases, except those made by speculators to support the market, are noticeably absent; this is only to be expected while the stock of rupees in the Indian treasuries is so plentiful. The stock in Bombay is slightly higher in value—£320,000—as compared with £290,000 last week. The offtake is about the same. The centre of interest lies rather in China, where it is said that the harvest has been good as a whole. On this account, in normal circumstances, there would be an exception of rising exchange, with the possibility of a demand for silver, but, unfortunately, as yet, trade is far from active. Shanghai reports a stock of £5,750,000, and increase of £100,000.

QUICKSILVER

The primary market for quicksilver is San Francisco, California, being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

TIN

New York prices control in the American market for tin, since the metal is almost entirely imported. San Francisco quotations average about 5c. per lb. higher. Below are given average monthly New York quotations, in cents per pound:

Monthly averages.

	1912.	1913.		1912.	1913.
Jan.	42.53	50.45	July	44.25	40.70
Feb.	42.96	49.07	Aug.	45.80
Mch.	42.58	46.95	Sept.	48.64
Apr.	43.92	49.00	Oct.	50.01
May	46.05	49.10	Nov.	49.92
June	45.76	45.10	Dec.	49.80

According to L. Vogelstein & Co.'s report, dated August 1, it is difficult to draw conclusions concerning the probable future course of tin prices. Several facts, however, stand out distinctly. These are as concern supplies, that Straits' shipments to date are 2251 tons larger than for the corresponding period in 1912; that arrivals of Bolivian tin and tin ore in England and on the Continent are 2191 tons larger. On the other hand, Banca sales to end of July are 900 tons less than last year and Australian shipments 370 tons less; the net increased supplies from these sources being 3172 tons. Deliveries in the United States for seven months fell off 1800, and in London and Holland 550 tons; while other supplies in Europe seem to be holding their own; the net decreased deliveries being 2350 tons. The result is that, whereas the visible decreased 3168 tons, from January 1 to July 31, 1912, this year it has increased 1086 tons, a net

change for the worse of 4254 tons. Against this may be set the fact that the visible is still nearly 1300 tons less than at the corresponding time last year, while prices are £23 per ton lower in London, and 5¼c. per pound lower in New York. This fall in prices would seem to have discounted the relatively unfavorable showing of the metal except for this tendency of statistics to continually deteriorate, which will eventually result in an accumulation of stocks. Minor fluctuations will probably take place until the situation is more clearly defined.

FOLLOWING the strike of the Lake Superior miners, copper prices took a sharp upward turn, reaching 15c. per lb. the last week in July, and continued upward to 15¼c., where it was firmly held on August 2, the American Smelting & Refining Co. asking the equivalent of 15¾c. abroad. Since buying was resumed, over 150,000,000 lb. of copper has changed hands, mostly for the account of foreign consumers. The foreign buyers, indeed, are reported to be trying to buy for deliveries up to January 1 next, but have been unable to get beyond October copper. The London market showed a decline toward the end of the week, but this was entirely speculative and had no effect in New York. At this writing, the Lake Superior strike promises to be protracted, and it must be remembered that its effect on stocks will be almost immediate, for not much of the Lake copper needs refining. This takes 18,000,000 lb. of copper off the monthly output, and as it will be a month yet before the Nichols refinery is back to its normal output, next month's figures should show a marked effect. Exports of copper for July, as reported by the Custom House, were 65,000,000 lb. Speculations as to the Copper Producers' figures for this month incline toward a 15,000,000 lb. increase in the surplus. Shares in copper mines elsewhere than in the Lake district rose as a result of the better price of copper, and the temporary disqualification of the Lake mines. Speculators in Lake shares are wondering whether the lowered price of Lake issues is only temporary or whether it presages a permanent decline in the importance of the Lake district. Either in sympathy with copper, or because of the good demand and small stocks, lead has also advanced from 4.35 to 4½c., the American Smelting & Refining Co. having set the price of pig lead at the latter figure.

THE half-yearly reports, to June 30, 1913, of several of the Lake Superior copper companies contain the following information:

	Ahmeek.	Centennial.	Superior.
'Rock' stamped, tons	322,551	62,323	76,572
Copper produced, pounds...	7,893,340	1,135,000	1,705,000
Mining cost per lb., cents...	6.03	10.50	10.72
Construction	2.71	0.68
Smelting, freight, etc.....	1.27	1.65	2.15
Total cost per lb., cents.			
	10.01	12.15	13.55
Profit	\$421,000	\$32,000	\$37,000
Dividends	350,000

JULY COPPER PRODUCTION

	Pounds.
Anaconda group	22,100,000
Chino	4,831,185
Miami	2,890,000

On August 4 the Bunker Hill & Sullivan Mining & Concentrating Co. paid dividend No. 191, of \$65,400. This makes the total amount of dividends paid \$14,434,950.

Company Reports

FEDERAL MINING AND SMELTING CO.

Earnings of the Federal Mining & Smelting Co. for the six months, September 1, 1912, to March 1, 1913, were approximately \$520,000. This averages \$86,500 per month, or at an annual rate of 8½% on the preferred stock. The Company is now paying 6% on its preferred stock. The Company has entered into agreements to purchase several new properties, details and the arrangements of which are as follows:

The interests of Richard Wilson and Walter McKay in the Cleveland group of claims, situated near the town of Mace, and adjoining the Standard-Mammoth, were purchased on September 14, 1912, for the sum of \$180,000 in cash. Negotiations for the purchase of these interests had been carried on for several years. The interest purchased by the Federal company was thereupon consolidated with the remaining interests in the Green Hill Cleveland claims and put into a company called the 'Green Hill Cleveland Mining Co.', which started operations toward the end of September. The Federal company has already received back its \$180,000, and the property of the Green Hill Cleveland Mining Co. is now in position to earn and pay substantial dividends to its stockholders; the Federal company being the owner of one-half of the capital stock.

Negotiations for the purchase of the Helena-Frisco property at Frisco, which is adjacent to the Mace properties, have been carried on for several years and were completed on December 12, 1912, by the payment of \$100,000 and an agreement to expend \$150,000 for development purposes and in the rehabilitation of the mining plant. This property contains a large tonnage of zinc ore, value of which is in excess of the total of the above figures, according to the estimates of reliable engineers. Possibilities for exploration and development of the new vein, called the Cape Horn vein, recently discovered therein, together with the prospect of finding orebodies in a second known vein, called the Black Bear vein, should result in great benefit and advantage to the Federal company.

Between January 13 and March 14, 1913, negotiations were concluded with more than 96% of the stockholders of the Star Mining Co., a property near Mullan, and adjacent to the Morning and You Like mines of the Federal company, for an option to purchase their stock in the Star Mining Co., conditioned upon certain payments to be made and work to be done by the Federal company, over a period of about three years. The first payment was 1c. per share and did not exceed \$10,000. Under the terms of the option, the Federal company has the right to enter into the property of the Star company and do what exploration and development work it considers necessary. By reason of the fact that the mining property of the Star company is contiguous to the Morning mines of the Federal company, the development work upon the property of the Star company can be advantageously and economically conducted by extending the work of the Federal company in its Morning mines into the property of the Star company.

The Federal company has obtained an option to purchase at least 51% of the capital stock of the Flynn Group Mining Co. Part of this stock has already been issued to the stockholders of that Company and part of it is treasury stock. Under the terms of the option, the Federal company has the right and privilege of expending all the money paid by it for the treasury stock in the development of the property owned by the Flynn company. This property is adjacent to the Frisco property, and will be developed by the extension of the underground workings of the Frisco. The orebodies of the Frisco and Flynn properties run very high in zinc. The Federal company has no contract for its zinc ores and sells them in the open market. The zinc product of the Morning mines goes at the present time to the plant of the Beer-Sondheimer Co. at Bartlesville, Oklahoma. It is expected that the Company's policy of extending its holdings without spending or risking any considerable amount of its surplus, will be continued.

BULLFINCH PROPRIETARY (W.A.), LTD.

This Company was formed in 1910 to acquire the Bullfinch gold mines, about 138½ acres, in the Yilgarn goldfield, Western Australia, on the railway line from Perth to Kalgoorlie. The report for 1912 gives development work for the year as 4123 ft., which with 1085 ft. of diamond-drilling gives a total of 5208 ft. The gold content of the No. 1 series orebody was disappointing, but developments on the No. 3 series were satisfactory. The vein in the north-west drift, 447 ft. north at 310-ft. level, which has been driven on for 28 ft. and averages \$15.60 per ton over a width of 68 in., with ore standing in the sides, seems to be a strong body of quartz with the appearance of persistence in depth. Ore reserves above the 210-ft. level total 158,313 tons averaging \$12.42 per ton. Owing to the draining of the salt water supply in the mine, it was necessary to approach the Government for a permanent water supply. The laying of the government water pipeline is now completed. Development has been restricted

BEGINNINGS OF THE BULLFINCH.

owing to the concentration of labor upon the completion of the plant. The plant commenced crushing on February 15, and for the first period of six weeks to the end of March 1913 crushed 5178 tons, giving a profit of \$49,000. The April crushing returned a profit of \$39,000 from 4343 tons. Up to May 30, 1913, 15 stamps and one tube-mill have been running, and 5 more stamps and another tube-mill are now being installed. When these are completed a mill capacity of 6000 tons of ore monthly is expected. Diamond-drilling work to obtain a water supply was carried on during the year, nearly 1100 ft. of hole being drilled without results. The balance-sheet shows assets of property account \$11,929,000; machinery and plant, \$230,000; buildings, \$29,000; shaft-sinking, \$29,000; mine development and general expenditure account, \$182,000; stores, etc., \$31,000; a total of \$2,430,000; and liabilities of issued capital, 476,150 shares at \$4.80 each, fully paid, \$2,285,520, and sundry creditors, \$28,500.

KYSHTIM CORPORATION, LTD.

KYSHTIM MINING WORKS CO.

The Kyshtim Corporation, with a capital of £1,260,000 in £1 shares, was formed in 1908, to acquire the Kyshtim Mining Works Co. which was organized in Russia in 1900, and owns copper mines and smelters, iron mines and smelters, gold deposits, timber and forest land, and ranch lands, in the Government of Perm, in the Southern Ural mountains.

The report of the Kyshtim Mining Works gives the gross receipts for the year as £1,221,379, against total expenses of £752,978, resulting in a profit of £468,401 for the year. The most important branch of the Company's operations is now the copper department. Special attention has been devoted to the work of searching for and prospecting new ore deposits, and last year this work met with conspicuous success in the discovery of the Amerikansky mine, situated in the Soymanofsk valley near the present mines and smelter; preliminary prospecting and development work here have so far proved the existence of more than 500,000 tons of ore, probably of somewhat higher

value than the average of the ore from the other mines. The total reserves of copper ore now amount to more than 2,500,000 tons, averaging about 3% copper, 0.1 oz. of gold, and 1 oz. of silver per ton. With a view of proving the persistence in depth of the present known copper deposits, extensive drilling operations have been authorized, by which drill-holes to a depth of 1500 ft. will be put down on these deposits. Smelting is now concentrated at Karabash; at Upper Kyshtim works where, up to April of last year, blister copper was also being produced, only flue-dust and fine ore are now being treated in reverberatory furnaces, and the matte thus produced is shipped to Karabash for treatment in the blast-furnaces. Three McDongall roasters for fine ore have been installed at the Upper Kyshtim works. The capacity of the Karabash plant was increased in 1912 by the addition of a third water-jacketed furnace. During the current year the construction of a reverberatory plant at Karabash for the treatment of flue-dust and fine ore will be undertaken, and also the installation of six McDongall roasters to serve the reverberatory with hot calcine. The completion of this work will admit of a yearly production of about 10,000 tons of copper from the Kyshtim estates. All the copper produced is electrolytically refined at Lower Kyshtim works. In 1912 the Company produced 7547 tons of electrolytic copper; including slime recovered from the refining of copper, the profit amounted to £538,563. Mining costs show a small increase, as was to be expected with increasing depth; smelting, an increase of 8 pence, due chiefly to increased cost of fuel and flux at both smelters. The net cost, after deducting the precious metals, was £22 per ton in 1912. The total profit of the iron department was £26,274. For 1912 the trading profit realized by the forest department amounted to £8705, and also 19,577 tons of barren pyrite was sold in 1912, showing a net profit of £5811.

MONTGOMERY-SHOSHONE CONSOLIDATED MINING COMPANY

The stockholders present at the February 14, 1912, meeting of this Company unanimously voted to sell all the machinery and other perishable or removable property of the subsidiary companies in the state of Nevada and to pay the proceedings over to the Consolidated company on account of their existing indebtedness to it. This would render it possible to reduce expenses substantially; to leave in the treasury of the Company an amount sufficient to protect the interests of the stockholders of this Company for a period of years, pending any possible future developments which might give value to the mining or other properties of this Company, and to use the balance to wipe out the existing indebtedness of the Consolidated company by a composition or settlement, thus leaving the Consolidated company out of debt, and insuring the return to its treasury of the stock of the subsidiary companies now pledged as collateral.

The following is a consolidated statement of the cash transactions of this Company and its subsidiary companies during the calendar year 1912:

Aggregate of cash in treasuries on January 1, 1912		\$25,364
Receipts from sales of machinery, equipment and supplies	9,489	
Receipts from interest, rentals, and miscellaneous minor items	793	
Total		\$35,646
Western expenses	\$5,426	
Eastern expenses	1,804	
Old accounts paid	506	
Payments on account of contract above referred to	\$8,443	\$16,179
Balance in treasuries		\$19,467

Of the above balance \$13,463 has been invested in U. S. Steel Corporation sinking fund 5% coupon bonds and the remainder consists of cash in bank and on hand.

BRITISH BROKEN HILL PROPRIETARY CO., LTD.

This Company operates a silver-lead-zinc property in New South Wales, and the report covers the half-year ended December 31, 1912. The general manager, C. J. Emery, reporting on the operations for the half-year, states that the greater part of the development work was carried out around Thompson's shaft, in the main orebodies. A later report is issued by G. C. Klug, the managing engineer for Bewick, Moreing & Co. The general testimony is to the satisfactory development of the mine, auguring well for the realization of anticipations regarding the continuity of ore lenses north of Thompson's shaft. The southern part of the western lens is merging into a large body of rhodonitic low-grade sulphide ore, but the lens itself is continuing with depth, on a fairly flat angle of pitch. The eastern lode-channel is proving itself consistent, and several lenses of milling ore are being developed. On No. 10 level, the lowest in the mine, the cross-cut had intersected the southern portion of the main western orebody. As in the upper levels, this orebody was of a rhodonitic nature. The cross-cut also passed through a lens of good ore in the east lode-channel. From the evidence revealed by this cross-cut, it is apparent that the western and eastern orebodies are approaching each other in depth.

The development of the northern portion of the mine is

BROKEN HILL DISTRICT.

of great importance, and a satisfactory arrangement has been made with the Junction company, whereby this work can be started from Browne's shaft at No. 6 level. The mine is opening well on No. 2, 3, and 5 levels, south of Thompson's shaft; and in the south end of No. 2 level ore has been opened in the eastern lode channel.

It is intended to remodel the lead mill, and install the Minerals Separation process in the zinc plant. Tube-mills will be installed and concentrating tables increased. The remodeled treatment plant should have a capacity of 20,000 tons of ore monthly. Operations resulted as follows:

Development, feet	1,955
Diamond-drilling, feet	4,288
Ore reserves, tons	2,000,000
Ore milled, tons	103,680
Average content:	
Lead, per cent	13.2
Zinc, per cent	11.7
Silver, ounces	7.3
Lead concentrate produced, tons	15,003
Recovery of lead, per cent	68.8
Zinc tailing treated, tons	49,238
Zinc concentrate produced by Elmore process, tons	13,386
Average content:	
Zinc, per cent	40.2
Lead, per cent	11.7
Silver, ounces	11.4
Recovery of zinc, per cent	78.0
Metal production:	
Lead, tons	10,989
Zinc, tons	6,379
Silver, ounces	516,096
Revenue from concentrate sales, etc.	\$912,000
Profit	293,000
Dividends (reserve account drawn on to make up)	518,000
Surplus of liquid assets	734,000

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

SLATE AND SHALE are used to a considerable extent in the manufacture of pigments and as fillers in the manufacture of oilcloth and linoleums.

CONCRETING the 5-compartment Junction shaft of the Calumet & Arizona company, which was commenced at the 1500-ft. point eight months ago, is now within 250 ft. of the collar, and should be finished in 30 days.

ELECTRIC POWER is supplied the Arizona Commercial mine by the Old Dominion company for hoisting at 2.5c. per kw. hour, and compressed air for pumping and drilling at \$35 per 1,000,000 cu. ft. of free air. Pumping is to be done by electric power instead of air.

ORE TRANSPORT from the Hannan's Star mine and the Lake View mill, Kalgoorlie, a distance of one mile, is done by means of a 9.5-ton Koppel locomotive and side-tipping cars of 2.1-ton capacity. The costs are per ton of ore: labor, 1.80c.; repairs, 1.16c.; fuel, 0.74c.; and stores, 0.28c., a total of 3.98c. per ton. The quantity of ore carried averages 9615 tons per month.

FURTHER experiments with the volatilization process at the Gwalia Consolidated mine, Western Australia, are encouraging. Apparently the antimony in the ore aids volatilization of the gold, as tests hitherto have not been successful in roasting clean pyritic ore with salt. At Hillgrove, New South Wales, metallic antimony reduced from flue-dust (oxide of antimony) contained an appreciable quantity of gold.

EXTENSIVE experiments are being made for the purpose of securing a higher extraction from the manganese ores of El Favor mines, Jalisco, Mexico, and several promising methods are now being tried, the best of which seems to be from the work of the Massachusetts Institute of Technology where tests indicate that a much higher percentage can be saved through magnetic concentration. This process is now being thoroughly tried by Walter Neal.

CHINESE AND FOREIGN CURRENCY is to be excluded from Hongkong. The standard of currency since 1895 has been the British silver dollar, equal to about 48 cents United States currency. It weighs 416 gr. and is 900 fine. There are also the 50, 20, 10, and 5c. silver coins, and 1c. copper pieces, and were made by Indian mints. Of course, the British sovereign, \$4.86, passes at Hongkong. On December 31, 1912, there was in circulation in the colony \$36,992,370 in Hongkong currency.

STOPES in the Chief Consolidated mine, Utah, are large as a rule, being from 40 to 50 ft. in width, and they are carried from level to level as the ores make in vertical position. It is the plan to fill in all stopes to within one set of the backs, thereby eliminating any possibility of injury to the men and any loss of stopes and ore as might occur at any time under the old system. The lime walls are very unstable and full of irregular fissures, which makes plain timbering insufficient at times to properly hold the ground.

ANALYSIS of a carload of ore from the Tough Oakes mine, Kirkland Lake district, Ontario, made by Campbell and Deyell, shows the following composition: SiO_2 , 78.45%; FeO , 2.90%; $\text{Na}_2\text{O} \cdot \text{K}_2\text{O}$, 2.62%; Al_2O_3 , 5.92%; CaCO_3 , 2.75%; MgCO_3 , 2.75%; MnCO_3 , 0.26%; FeCO_3 , 0.21%; CuFeS_2 , 0.09%; FeS_2 , 3.20%; Ag_2S , 0.14%; MoS_2 , 0.68%; PbTe , 0.17%; and alloyed metals, gold, 0.008%, and silver, 0.077%; a total of 99.975%. The altaite is a lead telluride, and no trace of gold was obtained from it, and less than 0.5 oz. per ton of the mineral in silver. The dark mineral in the ore, supposed to be graphite, was molybdenite.

EXPERIMENTS were made by the Phthisis Prevention Committee of the Rand to find out the amount of dust at different times, before blasting, after blasting, during drilling, and so on. They show that the most serious dust is created by the blasting, and then by drilling. Repeated microscopic examination of lungs of silicosis victims have been made, and comparisons have been instituted between the physical characteristics of extraneous mineral matter in these lungs and the dust arising from various mining operations. At the present time it may be provisionally stated that dust originated by blasting most closely resembles the dust incarcerated in silicotic lungs. Dump dust, dust from compounds and streets, are not characteristics present in silicotic lungs.

FREQUENT mistakes are made in examination of rocks, according to H. A. Buhler, state geologist of Missouri, and mining swindles are promoted thereby. Dark, fine-grained igneous rocks have been passed off as valuable tin ore; the yellow color of pyrite has been taken for gold; a yellow stain on rocks passed as gold; also small specks of yellow mica have caused much excitement; white marcasite, a sulphide of iron, is often mistaken for native silver; many green silicate minerals are often taken for copper ore; limestone and chert are mistaken for carbonate of zinc and lead sulphate; and many oil excitements are the result of finding a slight scum on the surface of stagnant pools, caused by iron. It may also be stated that tellurides of gold and silver are often suspected in rocks containing specular iron.

PLUMBAGO is a considerable source of revenue to the Ceylon government, as there is an export royalty on it of 0.25 rupee per hundredweight (about 8½c. per 112 lb.). It is Ceylon's most important mineral product. For the benefit of the industry, the Government arranges for the inspection of every working plumbago mine once in six months. The miners are advised generally as to their operations, and no mine is allowed to be worked which is considered unsafe. Information is afforded as to the mineralogy of plumbago districts. Skilled plumbago miners work for about 25c., laborers for about 17c., and cleaners for about 6c. per day. During 1912, exports of the mineral from Ceylon totaled 73,420,800 lb., valued at \$2,782,262, of which the United States took about 40%, most of the balance being taken by Germany and England.

Selective mining has received attention on the Rand, and an attempt to justify its introduction was made as a reply to the criticisms advanced against it by Lord Harris at the last annual meeting of the shareholders of the Consolidated Gold Fields of South Africa. No one can reasonably object to the adoption of selective mining methods when the gold contents and mining conditions justify it, but even the mines controlled by the Rand Mines, Ltd., although comprising nearly all the higher-grade mines, do not in every instance lend themselves to its successful adoption. The pioneer of selective mining among the Rand Mines group was the Village Main Reef, where at the present time the average monthly working profits have been reduced to \$144,000 from \$240,000 six months ago, and it is doubtful whether the higher level of profits will ever be reached again. Another mine belonging to the same group, the Geldenhuis Deep, was attempted to be worked by selective mining with disastrous results, while the reversion to normal methods of mining has practically put the mine on its feet again. It is therefore evident that, even among the mines controlled by the Rand Mines, the adoption of strict selective mining will not always bring the anticipated success; and, as pointed out at the meetings of the Consolidated group, there are many low-grade mines on the Rand where the adoption of selective mining is quite out of the question. No one can, of course, dispute the fact that in numerous cases broad selective mining is unavoidable, but when it is adopted with the object of temporarily increasing the profits and to influence the market, it cannot be too strongly condemned.

Production Statistics

ANTIMONY

No antimony has been produced in the United States from domestic ore and no domestic antimony ores have been mined and marketed since 1907, so far as can be learned by the United States Geological Survey, though a little metallic antimony was at one time saved as a by-product in the electrolytic refining of lead ore. None was reported, however, as saved during 1912 or 1911, according to Frank L. Hess. Imports during the year were: metal and regulus, 13,936,873 lb.; crude antimony and ore, 1,562,066 lb.; and oxide and salts of antimony, 1,759,908 lb., with a total value of \$940,994.

ARSENIC

In 1912, as in the four preceding years, the only white arsenic (arsenious oxide, As_2O_3) produced in the United States was that made by the Anaconda Copper Mining Co., the American Smelting & Refining Co., and the United States Smelting, Refining & Mining Co. as a by-product at their smelters. They made a total of 3141 short tons, valued at \$190,757, an increase of about 9 tons in quantity and of \$117,349 in value over the record production of 1911, during which year the output was 3132 tons, valued at \$73,408. The prices given in the returns averaged 3.07c. per pound f.o.b. New York, but ranged from 2.43 to 3.28c. per pound. Imports of arsenic or arsenious acid were 6156 short tons, and 81 tons of paris green and london purple, valued at \$435,691.

SELENIUM

Only one smelting company reported the production of a considerable quantity of selenium in 1912, though one other company made a few pounds, and on this account the quantity may not be given. The value was estimated at \$2.50 per pound. No selenium is known to have been imported.

As heretofore, the selenium produced was obtained from the anode muds left in the electrolytic refining of copper. Although selenium minerals are rarely or never found in copper deposits, nearly all copper bullion made from sulphide ores carries a little of the element. At Ducktown, Tennessee, as at most places, selenium has not been detected in the copper ores, but some of the sulphuric acid made from the sulphurous gases is given a pink or reddish tint by selenium.

Selenium is used principally in making red glass, enamels, and glazes. Small quantities are also used in photometers and electric apparatus.

BISMUTH

No production of bismuth ore in the United States during 1912 was reported to the United States Geological Survey, but one lot which was taken from the Highland Mary mine at Leadville, Colorado, in 1911 was sold in 1912. The ore was rich in gold and carried 15.47% of bismuth in the form of carbonate.

The American Smelting & Refining Co. and the United States Metals Refining Co. both produced a considerable quantity of bismuth as a by-product during the year, and it seems possible that in time enough bismuth may be produced from the various smelters to supply the domestic market. Heretofore large buyers have claimed that they could not safely buy bismuth from American producers, for should they do so and should the American producers be unable to continue supplies, the agents of the foreign sellers would thereafter refuse to sell bismuth to them, and the lack of a constant supply has always been a possibility to be feared.

Bismuth occurs generally in small quantity, but in some lots in considerable percentages with gold and silver ores at various places in Colorado and other Western states, and with lead ores in Utah. When these ores are smelted the bismuth may be collected in the lead bullion. From this bullion the bismuth is obtained in the anode muds in electrolytic refining.

Bismuth also occurs with the copper ores of the Butte

region and, as has been frequently noted, in the aggregate a large quantity passes out of the smelter stacks with the fumes. Some remains in the copper bullion and is found in the anode muds of the electrolytic refineries. Imports were 182,840 lb., valued at \$316,440.

TALC AND SOAPSTONE

Talc and soapstone are closely related mineralogically. Talc is a definite mineral of which soapstone, as the term is generally used, is only an impure massive form, according to J. S. Diller of the United States Geological Survey.

Talc is a magnesium silicate, $\text{H}_2\text{Mg}_3(\text{SiO}_3)_4$, containing silica 63.5%, magnesia 31.7%, water 4.8%. It has a foliated structure, with pearly lustre on its cleavage face, greasy feel, and may be easily scratched by the thumb nail.

In talc-schist the folia of talc are arranged approximately parallel to the schistose structure and form rock masses that split readily into flat fragments. In other places the talc folia are not parallel, but lie in all directions, bind the mass more firmly, and give the rock a coarse to fine granular texture and a massive structure which characterizes soapstone (steatite), and enables it to be sawed into slabs for various manufacturing purposes.

Talc is generally mined in small fragments by underground methods, while soapstone is generally quarried in large blocks in open pits. The production of talc and soapstone was 133,289 tons, worth \$1,097,483, and 25,981 tons, worth \$609,480, respectively.

GYPSUM

Gypsum deposits are widespread in the United States. This mineral, in quantity sufficient to be useful, is reported as occurring in the following states: Alabama, Arizona, Arkansas, California, Colorado, Florida, Iowa, Kansas, Louisiana, Michigan, Mississippi, Montana, Nevada, New Mexico, New York, Ohio, Oklahoma, Oregon, South Dakota, Texas, Utah, Virginia, and Wyoming. The producing localities east of the Mississippi river are central and western New York, northern Ohio, two areas in the southern peninsula of Michigan, and southwestern Virginia. West of Mississippi river gypsum was mined in thirteen states in 1912. It is also mined in southeastern Alaska and shipped to a mill at Tacoma, Washington.

The production of crude gypsum reported for 1912 exceeds that of any previous year, according to the United States Geological Survey. The progress of the gypsum industry has been marked, although somewhat irregular. Increased production has not been recorded every year, but the gain made in good years more than offsets the decrease of less prosperous seasons. The number of short tons of raw gypsum mined in 1912 was 2,500,757, an increase of 176,787 tons over the 2,323,970 tons mined in 1911. The gypsum sold without calcining and used principally as land plaster and as an ingredient in portland cement and in paint, amounting to 441,608 short tons, valued at \$623,522, showed an increase in quantity of 54,128 tons, and in value of \$34,043, as compared with 387,480 short tons, valued at \$589,410 in 1911; and the material calcined for plaster increased in quantity 133,256 short tons and in value \$67,830. The total value of gypsum and gypsum products in 1912 was \$6,563,908, as compared with \$6,462,035 in 1911, an increase of \$101,873.

Imports totaled 412,697 short tons of unground and 3702 tons of ground or calcined gypsum, together with \$38,589 of manufactured plaster of paris, was valued at \$488,481.

INFUSORIAL OR DIATOMACEOUS EARTH and tripoli produced in the United States in 1912 was valued at \$125,446, compared with \$147,462 in 1911. The earth is largely used as an absorbent of nitroglycerin in dynamite manufacture. It is composed largely of silica, is a variety of opal, and represents the remains of certain aquatic forms of plant life known as diatoms. Tripoli is a light, porous, silicious rock, supposed to have resulted from the leaching of calcareous material from the silicious limestones, and is used as an abrasive, in the manufacture of filters, and in the paint industry as a wood filler and for enameling.

MINING AND SCIENTIFIC PRESS

"Science has no enemy save the ignorant."

Whole No. 2769 VOLUME 107

THAT the United States has no monopoly on the conservation movement is evident from a recent report from China to the effect that the new republic is adopting conservation measures for the protection of natural resources in the Hwai River basin.

AS a profitable field for legal exploitation, mining and the allied industries are at present supplying bonanza claims. Just why a small fee of \$100,000 should be considered exorbitant and out of the ordinary for patching up a difference between two mining companies is a question which the courts of Utah will decide in the near future.

THE California State Mining Bureau is about to undertake the preliminary work involved in a thorough examination of the mineral resources of the state. As this work is the first of its kind to be undertaken since 1896, such a report will be a welcome addition to the literature and information now available on the subject. The program includes a detailed canvass of the mines, quarries, and mineral springs as to their present status and future possibilities.

THE last report of the Mount Morgan Gold Mining Company shows that this famous old Queensland property is far from that stage of existence which would warrant Oslerization. With a past record of £8,079,166 paid in dividends, and the present rate of 20 per cent on a capitalization of £1,000,000, together with 3,526,000 tons of auriferous copper ore in reserve at the beginning of the year, the property is far from being 'played out.' The grazier who sold this property to the Morgan brothers in the early eighties for £640 evidently did not realize that the lamb with the golden fleece was within his fold at that time.

IN the ordinary conduct of mining operations it is seldom that a prospect becomes a mine, and more seldom that a prospect becomes a dividend paying investment. The fact that there are, however, notable exceptions to the rule, has made possible the mining industry as we have it today, as well as resulting in financial gain to at least some portion of the investors. As a property belonging to the latter class, we take pleasure in recording the mining and milling operations of the Seoul Mining Company in the present issue, which in less than four years has paid the shareholders in dividends the total of the \$400,000 of the stock issued. While Korea is not numbered among the important mineral producing countries of the world, the explora-

tion and development work which has been done in recent years in that country would indicate that it does present great possibilities for the future.

THAT the federal ownership of railways is not always an ideal solution of transportation problems is being demonstrated in Argentine, where the administration of the national transportation system has recently been acknowledged a failure. The Government is now contemplating the rental of the national lines to private companies under leases of 60 years duration in the hope that a change of administration will result in the efficiency of this system being raised to the standard of those controlled by private enterprise. As railroads are the all-important factor in the development of natural resources, a change such as proposed that will result in the extension of the lines and the development of new territory will be welcomed by those having interests in that part of the world.

THERE seems to be considerable misunderstanding and some dissatisfaction with the new Alaska mining laws as passed at Juneau and which went into effect on August 1 of the present year. The law as applied to placer mining is a combination of the old and new federal codes, together with the new territorial laws which went into effect the first of this month. The chief clauses in dispute are those in regard to the power of attorney and the question of assessment work. Under the new law it is permissible for a locator with a recognized power of attorney in his possession to locate two claims for each power of attorney which is held, he being limited to two such powers of attorney. It is thus possible under the new law for one person to locate six claims of 20 acres each during each calendar month. It is required under the present law that, before the end of the year in which the claims were located, the locator do \$100 worth of assessment work on each individual claim which has been located. The law also provides that no placer claim can be patented which contains a larger area than that fixed by law nor which has a length that is more than three times its greatest width. This clause makes impossible the 'shoe-string' locations of former days.

Mexican Metal Production

As the mineral exported from Mexico presents a true index of production, it is interesting to note the figures as presented in a recent bulletin of the Department of Statistics of the federal government covering the first ten months of the fiscal year ended July 1, 1913. The gold exportation during this period amounted to \$32,863,703, which is a decrease of \$9,783,063, or about 22 per cent from the amount of gold exported during the same period of the preceding year. While silver exports show an increase of \$5,920,780 for this period, the increase is due solely to the great increase in the exportation of silver coin, and as a result this figure has no relation to the production. The silver bullion and that exported as concentrate and alloyed with other metals amounted to \$70,195,369, which is a decrease of \$3,526,768. Copper production, however, has

shown a notable gain, as is evidenced by an increase in the exports, for the period under review, of \$5,027,698 over that of the corresponding months of the preceding year. Copper has, of course, suffered less than the precious metals, in that the bulk of the output is obtained from a comparatively few districts which have been in almost continuous operation during the period: Cananea, Boleo, Moctezuma, and the Mazapil companies being the chief producers. The last Company has been forced to suspend operations recently because of rebel activity in the district, which will have an important effect upon the copper production of the country. Lead and zinc have shown a decrease of \$846,154 and \$206,272, respectively, for the ten months under review. This is equivalent to a 16 per cent reduction in the lead exports and a 26 per cent reduction in zinc. Graphite mining, while in its infancy in Mexico, has the best record of any of the metals from the standpoint of increase in production. While this branch of mining has not reached that state of productiveness where it has become an important factor in the mineral wealth of the country, it is, however, making a beginning even under existing conditions. The exports of graphite during the period under review amounted to \$222,346, as compared with \$16,200 for the same period of the preceding year. The gold exportation for the past ten years varies from \$23,857,612 in the fiscal year 1902-03 to \$62,090,505 in the year 1910-11, and the silver exportation varies from \$65,523,645 in 1904-05 to \$125,400,083 in 1905-06, which was an exceptional year from standpoint of output. The average exportation of silver during the past ten years has been about \$86,000,000 annually and that of gold has averaged about \$35,700,000. Although the reduction in silver and gold export is significant and indicates a decided decline in the precious metal mining industry during the past year, it is not as serious as might be expected under the conditions which have prevailed in Mexico.

Sulphuric Acid Leaching

By one of the frequent vagaries of circumstance it is with sulphuric acid leaching, which has been tried times without number with at best but limited success and most commonly with no success at all, that much of the most promising experimental work on the extraction of copper from its ores by wet methods is being done. On the face of it, this method seems the simple, easy, and obvious means to employ. It is one of the classic theorems of economic geology that iron and copper sulphides oxidize on exposure to the air, yielding free sulphuric acid which takes the copper into solution as sulphate and carries it away to take part in other reactions, possibly the forming of a rich copper orebody. At Rio Tinto this natural reaction is utilized in a metallurgical process for the recovery of copper, and from time immemorial it has been customary to recover copper from underground waters by causing them to flow over scrap iron. Except under special circumstances the use of sulphuric acid to dissolve copper from its ores, subsequently precipitating the copper from the sulphate solution, has miserably failed to

meet that inflexible definition of metallurgy as the art of making money out of ores. In attempting to make sulphuric acid the basis of a general process, such as the use of cyanide solution for the recovery of gold, a host of technical difficulties are met, many of which are apparently insuperable, that have so far, except under special circumstances, combined to prevent the successful use of this method. So much buncombe regarding leaching processes for copper is to be heard or seen that it will be well worth while to review the facts.

The first difficulty with sulphuric acid as a solvent for copper ores is that it will not attack metallic copper, fresh unaltered sulphides, or chrysocolla. The last is somewhat in doubt, as apparently the acid will attack some varieties of chrysocolla, though it is maintained, with some show of reason, that these are not true chrysocolla, but an intimate mixture of a large quantity of malachite with a small quantity of chrysocolla. Cuprite also is not soluble in sulphuric acid, though the oxide of copper formed in roasting sulphides is soluble. Now as a matter of practical fact, in dealing with a copper orebody of profitable size it is usually necessary to deal with the whole range of copper minerals, oxides, carbonates, silicate, metallic copper, and sulphides ranging from chalcocite to lean chalcopyrite. To attempt to use sulphuric acid on such a melange as this is like trying to put salt on the collective tail of Noah's ark. Where nature has been especially kind the use of sulphuric acid is feasible. Thus at Chuquicamata the copper occurs as a basic sulphate which is easily soluble in acid; at other places considerable bodies of carbonate ore occur and the amount of insoluble copper mineral present may be small enough so that the copper recovered may be enough to yield a working profit. At times an ore may be concentrated in the ordinary way, and leaching applied to the tailing, which is largely composed of oxidized minerals, as at the Arizona Copper mill at Clifton. But as a general thing the presence of metallic copper or unaltered sulphides will make ordinary leaching with sulphuric acid unprofitable.

Assuming that it is practicable to dissolve with H_2SO_4 the copper present in the ore, a fresh crop of difficulties is encountered. The acid not only dissolves the copper, but a variety of ore substances present in the ore as well. Thus clayey minerals will be attacked yielding aluminum sulphate, and iron oxides will be in part converted into ferrous sulphate. These and other substances remain in solution when the copper is subsequently precipitated and accumulate to such an extent that the solution becomes so foul that it must, in part at least, be thrown away. Sulphuric acid is now worth about \$7 per ton at the copper and zinc smelters where it is being produced; at more remote places its cost may considerably exceed this figure. It is easily seen that the cost per pound of copper for the sulphuric acid thus consumed is an important item of working cost. Various schemes have been tried to prevent this loss of acid, but no general remedy has yet been devised. The iron thus dissolved is a source of further trouble in case it is desired to precipitate the copper from the solution by means of elec-

trolysis. When the current is passed through the solution, copper is precipitated and SO_3 ions are released which oxidize the ferrous sulphate present to the ferric state, and the ferric sulphate promptly redissolves the copper, reducing itself to the ferrous state again. The ultimate result is much like that of a puppy chasing its tail, and converts the electric energy into useless heat. Some promising work is being done on the use of porous diaphragms to prevent the ferric sulphate reaching the cathode; but while effective these increase the resistance of the cell and merely alter the difficulty without solving it, though it is possible that a satisfactory solution may be found. Another troublesome difficulty in electric precipitation is the securing of a satisfactory substance for an anode. The best that has been found is lead, but even when this is used it is slowly converted into the peroxide of lead by the oxidizing reaction mentioned above and is gradually destroyed. The peroxide can be collected and reduced to metallic lead, but this operation forms another item of working cost.

It is possible to reduce the copper from the solution by causing it to pass over metallic iron. Theoretically, 56 pounds of iron will thus reduce 63 pounds of copper, but in practice this is greatly exceeded, for a certain amount of free sulphuric acid is present and dissolves iron, thus at once consuming iron and sulphuric acid. Pig iron is not very satisfactory for precipitation, since it contains phosphorus, sulphur, silicon, and carbon, and is, in addition, in the form of pigs which present only a small active surface in proportion to their mass. Scrap iron and steel are used for this purpose in small way, but a large plant would quickly exhaust the scrap heaps of the world. It is usual to reckon that three pounds of iron is required to thus precipitate one pound of copper, though much better records are made in many cases, and on this basis the cost of precipitate alone would be 3 cents per pound of copper. Some interesting work has been done on the roasting of pyrite to yield H_2SO_4 and the reduction of the resulting porous iron oxide to metallic iron in a reverberatory furnace, but even by this method the cost is still heavy.

Collateral with these fundamental difficulties are a variety of mechanical and chemical problems which vary according to local conditions. If the ore is ground fine the action of the acid on the gangue minerals is greatly increased and in addition colloidal material is produced which renders difficult the separation of the dissolved copper from the residue. It is reported that in the leaching work at Butte only 80% of the copper is obtained in the solution, the rest, though apparently dissolved, remaining with the ore. A muddy solution is obtained which leads to the inclusion of floating particles in the precipitated copper. On the other hand, if the ore is coarsely crushed these difficulties are avoided, but the copper may not be dissolved by the acid. But enough has perhaps been said to clearly indicate that sulphuric acid leaching, while applicable where conditions favor its use, has not yet been sufficiently developed to play any such part in the metallurgy of copper as cyanide does in that of gold.

The Simplification of Gold Ore Treatment

By A. W. ALLEN

The successful application of the cyanide process in the extraction of gold from a great variety of ores has led to much theorizing on the question of the simplification of treatment; and attention has lately been drawn to the so-called advantages arising from the abolition of amalgamation in favor of direct cyanidation, whatever the coarseness of the gold in the ore. As the matter cannot be satisfactorily disposed of by a few expressions of opinion it may not be inopportune to draw attention to the various considerations involved, and the probable advantages and disadvantages arising from such a change of policy.

System of Nomenclature

The actual treatment of a gold ore is generally preceded by a series of experiments; and the results of these and the deductions therefrom are embodied in a metallurgical report. I would like to suggest the adoption of some definite system of nomenclature in such reports because at present the advantages of thorough amalgamation are apt to be overlooked. A report of experimental cyanide treatment generally gives a misleading estimate of probable recovery; and too often the fact is overlooked that an additional percentage must always be deducted from possible solution before it can be compared with, or used in conjunction with, possible recovery. The assaying of the ore before and after experimental amalgamation, or the actual recovery of gold during experimental amalgamation, denotes an actual possible recovery or extraction in practice. The assaying of the washed ore before and after experimental cyanidation indicates nothing more than a possible solution of gold, and must be distinctly differentiated from a possible recovery. When the percentage of possible recovery by amalgamation is added to the percentage of possible solution by cyanidation the total is by no means a possible extraction of gold; but is less in error than the result of a direct cyanidation test where the solution of gold is made to indicate a possible extraction.

Simple Amalgamation

As a preliminary I would like to consider the use of the term simplification when used in connection with the suggestion of the abandonment of amalgamation in favor of all-cyanidation in free-gold milling practice. Simple amalgamation is too well known to need further description. Suffice to say the gold is obtained in its original state of purity. The method of recovery is by far the most direct and the most economical; and the actual mechanical losses before realization are so small that they may be left out of consideration. There is an actual recovery of the total extraction of gold; and in the great majority of cases there are no refining fees to pay on bullion so recovered. The so-called 'simplification' consists in the following as an alternative. The amalgamable gold is ground and agitated in cyanide solution and a certain percentage is

dissolved. The balance may be considered, so far as the treatment under review is concerned, as an unrecoverable loss; and is an actual addition to the residual loss which would have occurred had amalgamation been practised. The gold so dissolved is then, during the course of treatment, intimately mixed with the ore. Owing to the higher metal content in the pulp a higher cyanide strength is necessary, and this results in a higher chemical loss to the solvent. During treatment the stability of the solution is impaired by the increased metal content, and the premature precipitation rendered proportionately more probable. Filtration follows thickening and agitation, and the purpose of this step in the process is to remove as much as possible of the dissolved gold from the residue. The efficiency of this separation varies with the class of apparatus used and the condition of the pulp; but let it be noted that, given the same scheme of treatment and filtration, the loss in dissolved gold is strictly proportionate to the original value of the solution in the pulp. This dissolved gold loss may be as low as 1% of the dissolved gold in the cyanided product; or it may be as high as 10%. On a homogeneous pulp a high displacement efficiency may be obtained in various types of vacuum filters or in the frame filter-press. On a non-homogeneous pulp of too high a dilution, or in other types of filters or presses, the displacement efficiency may leave much to be desired.

Precipitation Losses

Zinc precipitation may be assumed to follow filtration. The increased gold content necessitates a higher free cyanide percentage in the solution entering the precipitation plant. This results in a higher zinc and cyanide consumption. A percentage of the gold is precipitated. Acid treatment of the zinc sludge may be assumed to follow, after which the precipitate is washed, generally dried, fluxed, and smelted. A certain mechanical loss during these operations is inevitable, and there is a further loss in slag and matte in which, even if time, trouble, and expense are unstinted, the whole gold content is unrecoverable by ordinary methods. A percentage is generally realized by direct sale.

When the elaborate method of cupellation, preceded by litharge smelting, is practised, the resultant bullion is high grade. Under ordinary conditions, however, cyanide bullion is lower in grade than the bullion obtained from the amalgamation process; and refining fees have often to be considered as an additional expense.

Enough has, I think, been said to show that the so-called 'simplification' cannot refer to other than to the elimination from the flow-sheet of fundamental units for the recovery of gold. In actual practice the solution of gold can never be more than partly successful; and unavoidable losses occur at every stage of a treatment process rendered more complicated by an unnecessary addition of gold to

the material being handled. The result is an eventual recovery of but a percentage of the gold which would have actually been obtained had amalgamation been practised.

Insistence on the theory that amalgamation is unnecessary is the natural sequence of milling in cyanide because, under such conditions, amalgamation must play a secondary part in the scheme of operations. The only direct argument which can be used against the practice of amalgamating a free-milling gold ore is that it is not up-to-date.

Treatment of Free-Milling Ore

For the purpose of comparison I append some theoretical estimates which will serve to illustrate my contentions as to the importance of amalgamation in the treatment of a free-milling gold ore. The ore is assumed to carry \$20 in gold, 50% of which may be directly recoverable by amalgamation. It is further assumed that the tailing can be cyanided and a solution of the remaining gold, to the amount of 90%, can be obtained. Before the gold is ready for a mint, a loss of 2% of all the gold which passes into solution is assumed. A solution of 98% of the amalgamable gold is assumed in the case of direct cyanidation.

1. AMALGAMATION AND CYANIDATION		
	Per ton.	Per cent.
Recovered by amalgamation	\$10.00	50.0
Dissolved by cyanide, 90% of \$10.....
Recovered by treatment, 98% of \$9.....	8.82	44.1
Total recovery	\$18.82	94.1
Loss:		
Dissolved and precipitated gold,		
2% of \$9	\$0.18	
Undissolved gold	1.00	
	1.18	5.9
Value of ore	\$20.00	100.0
2. ALL-CYANIDATION		
Amalgamable gold:	Per ton.	Per cent.
Dissolved by cyanide, 98% of \$10.....
Recovered by treatment, 98% of \$9.80..	\$ 9.60	48.0
Unamalgamable gold:		
Dissolved by cyanide, 90% of \$10.....
Recovered by treatment, 98% of \$9....	8.82	44.1
Total recovery	\$18.42	92.1
Loss:		
Dissolved and precipitated gold,		
2% of \$18.80.....	\$0.38	
Undissolved gold	1.20	
	1.58	5.9
Value of ore.....	\$20.00	100.0

These figures are, I think, as lenient as possible toward all-cyanidation, but by no logical rearrangement could they be made to show a result in favor of the abolition of amalgamation. An exceptionally high figure has been assumed for the solution of amalgamable gold; and the assumed loss (2%) of the dissolved gold is below the average.

It may be said that when the pulp is high in dissolved gold the filtration treatment might be preceded by a system of decantation, or decantation and replacement with barren solution, which would reduce the amount of dissolved gold in the pulp, and also the ultimate dissolved gold loss in the residue.

Such a method might be followed but it would be equally applicable in the case of the treatment of the tailing from the amalgamated ore; so that given similar schemes of treatment, better results would always be obtained from the handling of material from which the greatest quantity of gold had been removed before cyanidation was commenced.

In most gold ores the abolition of amalgamation prohibits the application of leaching to the sandy portion of the product. In an ore carrying high or coarse gold content it is rarely possible to obtain a sample from the tube-mill circuit (or from the classifier discharge when the tonnage is being forced), which does not contain, in the absence of efficient amalgamation, sufficient free gold in a condition to make the leaching of the sandy portion impracticable. Unless the sand and the accompanying gold is pulverized and flaked to an exceptional fineness there is a possibility of the residue, after a complete agitation treatment, showing free gold in the pan. This is the more liable to happen when the viscosity of the mill pulp is high on account of the presence of clay in the ore.

Use of the Tube-Mill

As already mentioned, the abolition of amalgamation is closely associated with milling in cyanide; and much of the benefit said to accrue from the latter practice when used in treating amalgamable gold ores is due to the fact that, with the abolition of amalgamation, the tube-mill assumes importance as a prime factor for the solution of the excess gold. The effective action of the pebbles in bringing the solution in contact with the gold admits of no doubt; neither is there any question that a considerable percentage of amalgamable gold can be dissolved in a tube-mill circuit using cyanide solution as a diluent. But from this fact can be adduced no argument in favor of the solution of gold rather than amalgamation; it indicates no economic advantage in neglecting to recover the greater portion of the gold in the shortest time and by the most direct method.

One of the most interesting examples of metallurgical advance is indicated in descriptions of the Dome mill, Poreupine, where the efficiency of modern equipment is helped by a combination with previously proved practice. From a published account* it is to be noted that a recovery of 95% is being obtained, and 65% of this is the direct result of amalgamation treatment. After the removal of the bulk of the gold it has been found that cyanidation is so successful that only economic restrictions limit the ultimate recovery which may, from all accounts, be raised at will to an exceptionally high figure. The question of leaching the fine sand from the milling plant has been raised and the thoroughness of the amalgamation treatment will doubtless make this an economic possibility. On the other hand, and although such minor modification may be instituted, it would seem impossible to improve upon the general scheme of treatment both as regards economy of method and efficiency of operation.

*H. A. Megraw, *Eng. & Min. Jour.*, Nov. 23, 1912.

Mining on the Suan Concession

The general report on the Suan concession by Hooper, Speak & Co., which is based upon an examination of the property made by A. H. Curtis, contains the following information on the present position of the Company.*

The concession is situated in the Suan district, Province of Hwang-Hai, Korea, the Suan mine, which is at present the only producing claim, is at Hol Kol, a village lying about due east of and 52 miles distant by road from Pyeng Yang, the sec-

other purposes from sources within or adjacent to the district.

A royalty of one per cent upon the gross value of the output of the mines is payable to the Korean government, also an annual mining land tax of 50 sen for each 1000 tsuho (say 25c. U. S. currency per 5/6 acre) of land actually selected for mining operations.

Korean Syndicate

The original concessionary was the Korean Syndi-

GENERAL VIEW OF THE SUAN HOLDINGS.

ond capital city of Korea. From Pyeng Yang (called by the Japanese 'Hei jo') there is railway communication northward with Europe, via Siberia, and southward with the Korean port of Fusan, whence there is daily steamship service across the Straits of Shimonoseki, Japan.

Topography

The concession is irregularly and ruggedly mountainous, with many valleys and detached groups of low mountains of peculiar forms, frequently conical, due to the erosion of easily crumbling rocks; and it is evident that eruptive action has played an important part in the formation of the region.

The ordinance for the concession, signed and sealed at the Foreign Office, Seoul, Korea, on November 4, 1905, gives full and exclusive rights and authority to examine, develop, and operate all mines and deposits contained within the district covered by the grant, with permission to cut timber and use all the water required for mining, milling, and

cate, which, however, leased its right to Collbran & Bostwick on November 12, 1907, at which time the prospects of success were not considered as encouraging by the syndicate. Under this leasing agreement it is provided that the Korean Syndicate shall receive 8% of the actual profits derived from the concession and all properties comprised within that area, these payments to be made clear of all deductions for depreciation of plant or property and for interest on capital.

All rights, title, and interest in the concession and property were transferred to the Seoul Mining Co. at its incorporation on April 27, 1908, in exchange for one-fifth of the capital shares of that undertaking, the authorized capitalization of which is 5000 shares of \$100 (U. S.) each. Of this capitalization, the Company's balance sheet for the year ended December 31, 1911, showed 4000 shares to have been issued. The earning of revenue by the Company practically commenced in January 1910, although 827 tons of ore from the Suan mine was milled during December 1909.

For the same periods, the actual operating costs,

*For further information, see 'Work of the Seoul Mining Company, Korea,' *Mining and Scientific Press*, June 7, 1913.

revenue, and gross profits at the Suan mine per ton milled were as follows:

(b) 'General expenses' include management and all office expenses; maintenance of agents at Pyeng Yang, Chemulpo, and elsewhere, and of president's and secretary's offices; bullion, surveying, hospital, legal, and traveling expenses, etc.

(c) 707 tons ore shipped to Tacoma, Washington, U. S. A.

(d) No ore shipped, but \$1197.39 over and above its estimated value received in final settlement for shipment in year 1910.

(e) 57 tons ore shipped to Liverpool.

(f) This is gross profit, no deduction being made in respect of royalty and taxes, improvements and buildings, or administration expenses.

Capitalization

As already mentioned, the authorized capitalization of the Company is \$500,000, of which the issued

work has been almost exclusively confined to the eastern half of the concession, in which portion a number of claims have been located along what is known as the Collbran Contact. The Collbran Contact may briefly be described as occurring between limestone of Paleozoic age and a deep seated intrusive boss, or batholith, of granitoid rock, which has tilted the limestone at varying angles and greatly altered it for a distance in general not much exceeding 200 ft. measured horizontally. As more or less defined by mining and prospecting work, the contact is roughly elliptical in surface contour, the major (east-west) axis being about 9 miles and the minor (north-south) axis about 7 miles in length.

The limestone rarely lies in immediate contact with the granite, being generally separated from it by a band of hard micaceous schistose rock, varying in width from a few inches up to several feet. This schistose rock is usually garnetiferous, and, on being reached when cross-cutting, no further attempt is made to find ore by an extension of the cross-cut. Masses of rock composed almost entirely of lime-garnets have recently been discovered in several parts of the Suan mine, actually in central

portions of orebodies. Seams containing garnetiferous matter have also been found at a distance from the schist lying next to the granite. Exposure, therefore, of the garnetiferous rock does not necessarily mean (as appears hitherto to have been assumed) close proximity to granite.

Contact Minerals

Among other contact minerals of more or less usual occurrence with deposits of this class are actinolite, biotite, chlorite, and talc, while fluorite in the rare octahedral form has recently been found.

Although the contact as defined by mining and prospecting work, has been referred to herein as being roughly elliptical in surface contour, it must not from this be assumed that its outline is regular; for observations show that the limestone is pierced in many places and directions by long tongues of granite protruded from the main mass, the eastern workings of the Suan mine being situated to the north of one such protrusion. Further, vertical cross-section around the contact would no doubt show that it has many variations of dip, the cross-sectional outline being in places nearly or quite horizontal—as evidenced by the flatness of dip characterizing lenses, more particularly in the western part of the Suan mine.

Speaking generally in reference to the orebodies occurring in the zone of mineralized limestone (extending, as already mentioned, for a distance of not much exceeding 200 ft. from the contact, measured horizontally) these may be described as a series of irregular masses in general parallel with the limestone granite contact in their respective vicinities, these lenses being in general connected by more or less well defined fissures or channels, in following which only occasional 'payable assays' may be obtained. There appear also to be certain transverse channels which may be assumed to have played an important part in the genesis of the ore-lenses.

In the case of the Suan mine, the rock constituting the gold and copper-bearing orebodies, is a highly silicious crystalline limestone, generally white in color, and containing a considerable amount of magnesia and alumina, also sulphides of iron—chiefly ordinary pyrite.

Valuable Content of Ore

The valuable constituents of the Suan ore are gold (fineness about 810 to 812), copper, and bismuth. Gold seldom occurs visibly and rarely in coarse condition. It is alloyed with an appreciable percentage of silver (not taken into account in mine estimates but paid for by purchasers of bullion) the ratio of weight of the former metal to the latter being about 4.6 to 1. The average fineness of Tul-Mi-Chung gold may prove to be considerably less than that occurring in the Suan ore, a test of 59 tons at the Sectarie mill in January 1913 having yielded bullion with a fineness of only 741.

Copper occurs chiefly as chalcopyrite, also as bornite and tetrahedrite. A high percentage of copper is usually associated with a high content of gold, although there is no fixed ratio between the amounts and, indeed, there are many exceptions to

the usual rule. On certain other claims, large quantities of magnetite occur in close proximity to the contact, and this mineral appears to have been extensively mined and smelted in earlier days by Koreans, as an ore of iron.

The Suan mine is situated at the village of Hol Kol, at the head of a short, somewhat steep, poorly watered valley formed by hills forking northward from a branch of the main mountain chain of the district. It is in this branch chain that the Collbran Contact occurs at Suan. The Suan mine has been developed and exploited to a vertical depth of about 300 ft. below the outcrop by means of cross-cutting adits and of levels driven therefrom. Below the deepest of these adits development and exploitation have been continued by means of an inclined shaft to a further depth of nearly 500 ft. measured on the incline. The development of the mine has been seriously retarded by the inadequacy of the air-compressing and rock-drilling equipment, as well as by the incapacity of the main shaft hoist (also operated by air) to handle any larger tonnage of rock than that actually required to keep the mill supplied.

A large compressor has arrived and a new hoisting engine has been ordered, of appreciably larger size than the one now in use. It should, therefore, be practicable with this new equipment to push mine development ahead more rapidly, and it is recommended that the present inadequate equipment of machine drills should be supplemented by at least an equal if not a greater number.

Development

The annual development footage since the commencement of operations has been as follows:

	Feet.
Previous to 1909	5,199.0
1909	4,929.5
1910	2,971.0
1911	4,694.0
1912	5,264.5
Total	23,058.0

The average monthly footage accomplished at any face by hand labor is about 20; raising (with Waugh drill) about 50; driving (with Siskal drill) about 80. The cost per foot of this work (which is done by Chinese and native contractors), including supervision and all other charges, cannot be exactly stated; but an idea of the cost may be formed from an inspection of contract payrolls for 1912, from which it appears that prices paid to contractors were in general as follows: driving, Y8 to Y10 (\$4.80 to \$5); cross-cutting, Y8 to Y9 (usually Y8); raising, Y8.

Prices do not include the cost of explosives, drill-steel, and candles, which were supplied by the Company at an advance on actual cost delivered at the mine. Contractors on development work are supplied by the Company with air-drills and compressed air, when the work requires the use of machines and these happen to be available.

Stoping was formerly done with the assistance of square-set timbering, which is probably the safest and simplest method of exploiting the wide ore-

bodies of the Suan mine. Owing, however, to the cost of squared timber of the necessary size becoming prohibitively high, the 'shrinkage' system of stoping was introduced throughout the mine.

The average number of men working daily at the mine is about 425, the number being made up approximately as follows:

	No. of men.
Stoping	100
Development	100
Tramming	40
Miscellaneous, including bosses, shovelers, coolies, blacksmiths, engineers, oilers, etc.....	185
	425

Labor is most plentiful between November and April; but the force appears to be reduced by about one-third during the summer months, when many Koreans go to the farms. Neither holidays nor labor shortage is a serious consideration at the Suan mine.

The Suan Orebodies

The orebodies that have principally contributed to the output of the Suan mine since milling was commenced are known respectively as:

- (1) The 'Eastern' orebody which occurs eastward of the main shaft;
- (2) The 'Central' orebody, lying to the west of that shaft; and
- (3) The 'Western' orebody (sometimes called the 'Southern') which occurs to the southwest of the 'Central' orebody.

In addition to these orebodies, subsidiary lenses and pockets of ore have been found and worked, or are in the course of development, the most important of these being one occurring a few feet eastward of the main shaft.

For the year 1912, the value of the bismuth recovered in concentrate was \$19,025 (\$0.25 per ton of ore milled), the weight amounting to 2.24% of the total concentrate made, or 0.023% of the ore

The bismuth content of the concentrate is determined monthly prior to shipment, by averaging the assays of three composite samples (each representing 10 days run of the mill). This is the only determination of bismuth made, neither the heads nor the tailing of the ore milled being assayed for that metal. It is, therefore, impossible to state the average percentage of bismuth in the ore.

The sources of amalgam recovery in the mill are as follows:

	Approximate percentage of total recovery.
Mortars	5.0
Upper Pierce amalgamators.....	79.0
Plates	1.0
Lower Pierce amalgamators	4.4
Tube-mill and Pierce amalgamators.....	6.0
Miscellaneous, including launder	4.6
	100.0

No attempt has hitherto been made to store tail-

SUAN MILL.

ing for future treatment. Official records show that the average head and tailing assays and percentage extraction, by means of amalgamation and concentration, for the years 1910-1912, were as follows:

Year.	Heads.	Assays.		Actual tailing.		Actual extraction.	
	Ore milled, tons (2000 lb.)	Gold, dwt.	Copper, per cent.	Gold, dwt.	Copper, per cent.	Gold, per cent.	Copper, per cent.
1910	32,793.3	11.88	1.43	2.10	0.96	78.03	18.32
1911	70,229.4	9.30	1.03	1.43	0.73	79.10	18.40
1912	74,432.0	8.53	0.89	1.30	0.65	86.20	20.34

milled. During the current year, the ore delivered to the Suan mill will be obtained almost entirely from the Eastern orebody, and probably in largest proportion from the North branch or branches, the average bismuth content of which has yet to be determined. It will be safe, however, to assume an average bismuth content of not less than 0.15% (3 lb. per short ton) for the entire output sent to the mill.

The concentrate (averaging for the year 1912, 0.99% of the weight of ore milled) contains gold, silver, copper, and bismuth. After being dried on a heated cement floor it is sampled and then sacked for shipment to Liverpool.

During three or four winter months, shipment of concentrate is impossible owing to the freezing of the river. The 'canvas' and 'black' concentrates are shipped together as 'black concentrate,' the 'regular' concentrate being shipped separately.

Water Storage

At present the only water storages on the concession are that provided by the Morachi dam for supply of water to the two boilers at the Suan mine power-house, and that at the Tolkokai dam for the purposes of the 40-stamp mill at Soetario. The amount of water required at the mill for all purposes, including boiler-feed, probably does not exceed 450 gal. per minute; nevertheless even this small supply is not always fully available during the winter months, owing to the freezing of the streams, none of which is of any considerable volume except when swollen by exceptionally heavy rainfall. The consequence is that from 5 to 20 stamps are liable to be out of operation during the coldest part of the winter, as actually happened recently.

After considering the power problem in all its aspects, the only conclusion at which it is possible to arrive is that electrical transmission from outside

the concession is the best solution, the point remaining to be decided, being whether such power could be more economically purchased than generated by a plant installed by the Company, having due regard to the prospective life of the mines. The maximum amount of electrical power likely at any time to be actually required to be delivered at the Suan and Tul-Mi-Chung mines and mills is about as follows:

	Kw.
Suan mine	190
Suan mill	225
Tul-Mi-Chung mine	225
Tul-Mi-Chung mill	225
Total	865

It has been estimated by the general manager that the total cost of the power plant and a single transmission line, including the sub-stations, transformers, instruments, etc., also construction and erection, but not including the motors and compressors, would not exceed \$250,000. There should, however, be no difficulty in obtaining a close estimate when a site for the power generating station has been definitely selected and the length of the transmission line is known.

Additional Equipment

It appears by no means unlikely that an increase in the size of the suggested ore treatment plant will be warranted by developments during the remainder of the current year, and the mill should be so designed and erected that additional stamps and concentrating plant can be placed to the best advantage.

For the deeper development of the Tul-Mi-Chung mine, it will be necessary to provide pumping machinery and plant of larger capacity than required at the Suan mine, the amount of 'backs' of ore obtainable above water level at Tul-Mi-Chung being comparatively small, although there is sufficient to furnish ore to 20 stamps for a considerable time.

The other claims located along the Collbran Contact have not yet been sufficiently explored to warrant the expression of a firm opinion with regard to their prospective value.

The Suan concession is a property of great potentialities. Already one mine developed thereon (namely, the Suan) has been successfully exploited for more than three years, and at the present rate of crushing, and without counting on future discoveries, there is enough ore (including probable ore) to supply the mill for 3½ years and longer. Another claim (Tul-Mi-Chung) has been already sufficiently prospected and developed to prove it to be of great value, and will become productive as soon as a mill can be installed.

The western half of the concession is not so encouraging, and may not prove valuable, at all events before the end of June 1916, when the Company must surrender such areas as it has not by that date delimited for mining purposes subject to the annual land tax. Therefore an active prospecting policy is strongly recommended and certainly no part of the concession in the immediate vicinity of the Collbran limestone-granite contact, perhaps 20 miles in length (which occurs in the eastern half of the concession), should be surren-

dered, since valuable ore deposits may be found in many localities around that contact.

Copper Production

The world's production of copper for 1913 is not likely to show any large increase over last year, and in a market letter on this subject Thompson, Towle & Co. predict that it will not exceed the 1912 production by 5%. Despite the fact that a large amount of new copper has come upon the market this year from the newer 'porphyry' mines, the total production thus far for 1913 of the United States, including two large Mexican properties, Greene Cananea and Moctezuma, is practically the same as that of the corresponding period of last year.

Outside of the United States labor troubles are playing an important part in the curtailment of copper, and the indications point to a still further reduction in the near future. In Australia some of the most important copper mines are now shut down. These include Mt. Lyell, Mt. Morgan, and many other large producers. An estimate of the copper curtailment now taking place at these properties aggregates approximately 5,000,000 lb. per month. This copper goes direct to Europe and while the figures will not be reflected in the refinery output of the United States, nevertheless their influence will be felt in Europe reducing its supply of the refined metal to that extent.

In the western hemisphere copper producers have been beset with many difficulties. In Mexico the political troubles have done much to curtail production. At the present time but one smelter of the A. S. & R. Co. is operating, that at Aguascalientes, and while this Company is working on supplies at hand and is still producing, a large number of the Company's mines have been closed and the copper output may be seriously affected unless operations are soon resumed. In addition to the A. S. & R. plants, Teziutlan and Mazapil, two of the largest copper properties, are shut down. These are the largest Mexican producers outside of those mentioned near the American border. In addition to these, probably many smaller properties are affected. Production from Greene Cananea at present is far below normal, and it is doubtful when this will be brought up to the rate predicted by the management for this year.

In the United States, labor troubles have brought about a still further reduction. A general strike has been called at the Lake Superior mines and the properties have all been shut down. This is one of the largest copper producing districts in the United States, and the closing of the mines will result in a curtailment of approximately 18,000,000 lb. per month. It will be seen from the above that the world's copper production for 1913 is not likely to be much in excess of 1912. When it is remembered that an increase in production of around 7% per annum is needed to provide for a normal consumption, it will be noted that production is not keeping pace with consumption and that from a statistical standpoint, the position of the metal for 1913 is an extremely strong one.

Mine Cost Keeping

By C. M. EYE

The importance of keeping a cost-system which will show clearly at any time just how the work is going, is now generally conceded by those in charge of mining enterprises. Just what the system may be, and how it is applied, varies with different enterprises, owing to local conditions and variations in methods. In order to get good results, however, the system must conform to certain principles. The figures must be reported daily from every department and promptly entered on the books. They must come from men in charge of departments and be vouched for by them. The system must be designed to give full data on every department without being too cumbersome and without requiring too much time for its preparation. The information should be as condensed as possible, and require as few forms as possible. There should be a check on the system to insure its accuracy; and, above all, the system of reports must correspond closely with the system of cost accounts adopted, which should be designed to show just what is required.

I recently had occasion to install a cost-keeping system where the operations were naturally divided into three distinct departments: mining, haulage, and milling, which are, of course, the most common divisions. Therefore, the three main operating accounts were carried under these heads as No. 1, 2, and 3.

No. 1 was subdivided into four sub-accounts, as follows:

- Account A—Exploration.
- “ B—Development.
- “ C—Exploitation.
- “ D—General charges.

No. 2 was subdivided into three sub-accounts, as follows:

- Account E—Train operation.
- “ F—Maintenance of way.
- “ G—General charges.

No. 3 was subdivided into four sub-accounts, as follows:

- Account H—Crushing and sampling.
- “ I—Reduction.
- “ J—Concentration.
- “ K—Cyanidation.

The following divisions of operation were made under No. 1: Breaking and handling; tramming; hoisting; timbering; pumping; track and pipe-laying; repairs and renewals; assaying; engineering; mine sampling; supervision. With following division of items of cost: salaries; labor; power and light; timber and lumber; explosives; candles; oil and waste; fuel; tools; steel and iron; miscellaneous supplies.

Under No. 2 were made the following divisions: Loading; hauling; unloading; repairs and renewals;

engineering; supervision. With following items of cost: salaries; labor; power and light; timber and lumber; explosives; oil and waste; fuel; tools; steel and iron; miscellaneous supplies.

The following divisions were made under No. 3: Receiving, weighing, and sampling; crushing; stamping; concentrating; fine grinding; elevating and dewatering; leaching (sand); discharging (sand); agitation (slime); filtration and discharging (slime); precipitating; recovery (clean-up and melting); marketing; assaying; engineering; repairs and renewals; supervision. With following cost items: salaries; labor; power and light; timber and lumber; explosives; oil and waste; fuel; steel and iron; zinc; cyanide; lime; screens; mill repair parts;

Daily Report Forms

In order to collect the figures daily for these accounts, and to furnish the manager with the information promptly and in a clear and comprehensive form, the above daily report form was designed. The arrangement and ruling is exactly the same for all of the operative reports. It is, therefore, possible to have a large number of forms ruled at one time, and then by the use of a small printing press at the works the forms can be printed in as needed, and the matter varied as changes are found advisable. Another advantage of the uniformly

ruled form is that the same class of information always appears on a given part of the form, so no time is lost in looking for the desired item of information. All of the desired information regarding a given department for a given day is on one report, and the various reports are easily compared and checked against each other as to results accomplished.

Various Uses of Report Form

The same form can be used with different printing for any other operation, such as the power-plant, or can be used for construction accounts equally as well. Of course, perfection is not claimed

Safety Electric Switches for Mines

By H. H. CLARK

*As a part of its investigation into the causes of mine accidents and the safeguarding of the use of electricity underground, the Bureau of Mines has recently completed a preliminary study of electric switches designed to prevent the ignition of gas by the spark that is drawn when such a switch is operated under a load.

Two general methods have been proposed to prevent switching flashes from coming in contact with gas that surrounds the switch. One method is to enclose the switch in a casing provided with openings that are covered with gauze or are otherwise designed and equipped, so that if a gas explosion occurs inside the casing the flames will be extinguished before they can reach the gas outside. Switches so protected are called explosion-proof switches. The other method is to immerse the switch contacts in oil to such a depth that the flash cannot reach the explosive mixture. Switches so protected are called oil-type switches.

The success of the first-mentioned method of protection depends on the proper design and construction of the switch casing. The merit of such design and construction can be determined by test. The successful operation of the second-mentioned method is dependent on the switch contacts being surrounded by the proper kind of oil in good condition. Switches of the explosion-proof type can be so designed that the condition of their protective features may be readily examined each time that the switches are operated.

The tests conducted by the Bureau seem to indicate that the oil switches will not ignite explosive mixtures of gas under the conditions described as long as

the switch contacts are covered with oil to a depth of 1/4 inch or more. This is best shown by the tests of the automatic oil switch in which the maximum instantaneous current was not far from 1000 amperes. The tests also show that the oil is not lost rapidly by evaporation nor by many operations of the switches under rated current load and at a voltage as high as the probable underground voltage in places where explosive gas is likely to be present. The tests show that the switch contacts deteriorated more rapidly than the oil. Even in the case of the automatic switch that finally ignited gas, several sets of contacts were burned off before the oil-level was so lowered that the gas was ignited.

It therefore seems reasonable to believe that oil switches will not ignite inflammable gas if they are designed with attention to the service that they are to perform and are inspected at reasonably frequent intervals. The tests demonstrate the possibility of constructing an explosion-proof type of switch that will not ignite gas.

*Abstract from Technical Paper 44, Bureau of Mines.

for this system. No doubt many changes can and will be made to advantage where it is being used, but one of the merits claimed for it is that the forms are easily and readily adapted to such changes as well as to desired extensions. Of course, certain of the cost items need not appear daily in the reports, but come to the proper main accounts by monthly distribution, such as salaries, power, and light. It is important to have a daily report from each department as to cost of labor and of supplies used, and as to what has been accomplished. I believe that these forms, properly used, will secure good results, and am therefore glad to place them before my fellow-workers with the hope that they may call forth comments and suggestions which will be of use to the profession.

The Great Cobar mine, New South Wales, produced the following during the first quarter of the current year: ore, 88,419 tons; blister copper, 1477 tons; gold, 6429 oz.; and silver, 25,000 oz. The revenue amounted to £147,000, mining expenses, £54,750, smelting, £30,670, and construction £15,000.

Under-Estimating the Cost of Milling Plants—III

By A. SYDNEY ADDITON

But little has been written, and no discussion carried on, in the technical journals upon the subject of underestimating the cost of mill construction, mainly for two reasons: those who have experienced heavy 'jolts' of cost have nothing to write about; those who have not had such experiences are too busy making installations to write about the other fellow's troubles.

Reasons for Excess Cost

Having, during seventeen years' experience as a metallurgical and constructing engineer, been called upon to examine many sets of specifications, plans, and estimates made by others, and the subject of cost always having been of special interest to me, I have gathered a large amount of data bearing upon this subject which may be of as much interest and possibly of more value, than any account of my visits to plants for the purpose of ascertaining the reasons for costs which exceeded the estimates. The reasons for excess cost are so many and varied that it will be necessary to take them up under the groups into which the work of making an installation might be divided.

1. Preparatory talk and discussion.
2. Arranging for finances.
3. Selection of engineer.
4. Examination of ore for treatment.
5. Additional talk and discussion.
6. Deciding on site.
7. Preparation of plans and estimates.
8. Securing of bids and buying material.
9. Clearing site and surveying.
10. Excavations.
11. Organization for installation.
12. Material yards, stock, and supply department.
13. Utilities during construction.
14. Crushing and concrete plant.
15. Foundations and retaining walls.
16. Equipment: (a) breaker plant; (b) sampling plant; (c) milling plant; (d) cyanide plant; (e) refining plant; (f) power plant; (g) heating plant; (h) lighting plant; (i) machine shop.
17. Buildings: (a) lumber (doors and windows); (b) iron and hardware; (c) structural steel (in case of steel frame).
18. Permanent utilities; water and air systems; fire system; assay plant; office; superintendence; supplies; labor; miscellaneous; freight and hauling.

Preparatory Talk and Discussion

Preparatory talk and discussion usually extends over quite a period of time and consists in taking up an unnecessary amount of the time of the manager or superintendent of the property in trips between the mine and city office, talking with machinery men, and securing prices of supposed requirements. All this costs money for no useful result and could be reduced by nine-tenths.

Arranging for finances is usually an expensive item involving trips to the East, commission allow-

ances for assistance, and so on. When done at this time it is largely a waste of money, as it is not known what amount is necessary, and the work will undoubtedly have to be done over again later on, when additional funds are needed. The second 'raise' usually costs more than the first, as money is wanted at once. The cost for this work can be greatly reduced by waiting until complete plans and estimates of cost are ready. A little delay at this point costs nothing beyond the engineer's salary, which he can generally be made to earn during this period to excellent advantage.

This item in itself incurs but little expense, but upon its careful carrying out depends the avoiding of great ultimate expense, and it is really the greatest factor in preventing an excess cost. The engineer must have both technical and practical experience, successful experience, business and executive ability, and enjoy the complete confidence of his principals. If the owner has not absolute confidence in the engineer and conversely, another should be secured, or excess cost may be expected. The engineer should be selected immediately on deciding to build a plant, or before.

Examination of the Ore

In the examination of the ore for treatment, the expense of sampling by the superintendent, foreman, sampler, or examining engineer, and the shipment of large samples to a metallurgical works for exhaustive testing, is entirely or largely wasted. The engineer employed to design and erect the plant must do it all over again, as he is not going to risk his reputation upon the results of work done by others. Therefore leave this work to be done by or under the supervision of the engineer who is expected to build an efficient plant. No attempt should be made to rush this work. This is most important and thoroughness is most essential, even at what may seem to be a high cost. Nothing can be saved here, except what is spent or wasted beyond payment for the conscientious service of competent men, who are expected to build the plant and be responsible for its efficiency. Much is often otherwise spent, and constitutes an excess cost.

Additional talk and discussion generally involves considerable delay and is more or less expensive and unnecessary. Visiting in the city by the manager, superintendent, or engineer, at company expense, discussing the proposed plant, and lunching with machinery dealers is a source of expense which could be eliminated.

Deciding upon millsite is not an expensive item, nor one that is apt to cause any excess cost, as the best site is usually evident. Special trips of the engineer from the city to the mine is about the only added cost that creeps in here. The engineer should be provided with facilities at the mine for preparing his plans, specifications, and estimates, since as the plans develop, an occasional reference to the site is quite necessary.

After the treatment of the ore has been determined upon, the preparation of plans, specifications, and estimates is most vital. Right here is where the excess costs should be avoided, but too often it is right here that excess cost is born. To enumerate the points wherein most estimates are deficient would be but to anticipate what is to follow: for all added costs, as taken up below, are due to lack of attention to this point. There is no reason why a plant should cost more than the estimate, if sufficient intelligent work is done upon plans, specifications, and estimates, barring accidents, strikes, or acts of God, which no one can foresee. The usual set of plans, specifications, and estimates consist of submitted prices of equipment, quoted freight rates, and roughly estimated labor costs, and are entirely lacking in detail (detail being worked out, if at all, as construction progresses). Such estimates are actually only preliminary, and the real work for which a high-priced man has been engaged is not done at all. No man can make a close estimate of cost in this way. Often it is an engineer's first construction work, and he cannot therefore be expected to 'guess' at a thousand and one items of cost with which he has never actually dealt. And even after he has designed and constructed many plants, his guessing is likely to be in error, as no two plants are alike or built for same duty or under same conditions. The reasons for so many incomplete sets of plans, specifications, and estimates are: attempt to rush, over-confidence on part of engineer, failure to see necessity for proper plans and estimates, and desire to save cost of preliminary work. All of these are also very good reasons for either failure or excess cost.

Purchase of Material

Securing bids and buying material is an important part of plant construction, where many dollars may be saved or wasted. To secure the best results the engineer who has made plans, specifications, and estimates, and is to supervise construction, must select his own equipment and material, and arrange for delivery, including routing of freight. Too often this is left to the president of the company, a director, or purchasing agent, with some of the following results: Articles are bought on account of some friendly or personal reason, others are substituted on account of a strong talk by a salesman or an attempt to save a few dollars; supplies are bought on account of best 'brokerage' paid; deliveries are made inconveniently; freight is shipped by a route different from that upon which the estimate is based, on account of the strong talk or friendliness of some railroad soliciting agent; goods are shipped in less than carload lots, when they could have gone in carloads; higher prices are paid than the goods could be bought for. An engineer can buy at lower prices than an owner, owing to the dealer's desire to gain the engineer's favor, in view of the future plants he will build, while the owner's buying is probably limited to the one plant. Besides all this, incidental expenses may be incurred in buying of which the engineer knows nothing, and for which he has made no allowance in his estimate. Not a dollar should be spent and charged to cost of installation which is

not either spent by the engineer or with his knowledge and sanction.

Excavations

Clearing site and surveying is usually left out of estimate entirely, and while it is not large, it is one of the many small items that swell the excess cost.

It is customary to estimate the cost of excavation by a price per cubic yard. So many yards of picking ground at so much per yard, and so many yards of rock at so much per yard. One common error in such figures occurs in cost per yard of rock; this cost being based on breaking solid rock of character known to exist on the site, overlooking the fact that rock found near the surface commonly breaks badly, being either short or blocky, and straightway driving can seldom be counted on. There is also much breaking up of pieces too large to handle, either by hammer or by 'bulldozing,' and much gathering up of rock blown into completed excavations; all of which is seldom counted on. Such figures are based upon the customary costs per cubic yard without going into the details of costs under the conditions actually prevailing, such as inconvenient dump-hand drilling or machine drilling (if latter, where is power to be derived from?); must temporary plant be installed for this, what portion of the plant can be utilized afterward, and what portion of its cost must be credited back to excavation, transmission of power (material, installing, wrecking, and loss of material); where will tools be dressed, must shop be maintained for purpose, and if the mine shop is to be used, how much must be paid to mine, water supply, how many cars, barrows, feet of track, barrow runways will be needed to suit conditions, cost of temporarily holding dangerous banks, finishing of grade and setting plugs, including surveyor's time. This common method of estimating may be found to be correct, where usual conditions exist, but it is dangerous, and if it is desired to insure against excessive cost, the details of the work in hand must be gone into thoroughly.

Organization

For economy and to insure the expected results the constructing engineer must necessarily be the one head to such an organization. The connecting link between himself and the company is the bank account. He must depend upon advices from the company as to when funds are to be available in order to be able to arrange contracts and payments to the best advantage. Other than this dependence, he should be free from company direction, except at such times as contingencies arise which may cause him to consult with officers of the company. The following organization of the work under the direction of the engineer is necessary to insure best results: assistant engineer, who should be the man expected to take charge of the plant as its superintendent later; general foreman of construction; master mechanic; boss machinist; boss carpenter; boss of erection (if steel frame construction); boss mason; boss pipe-fitter; boss tank builder; boss electrician or engineer; boss of common labor; boss yardman; storekeeper; tool and appliance man; surveyor; timekeeper; clerk in charge of orders and sup-

plies; clerk in charge of freight and hauling; clerk in charge of utilities; bookkeeper; draughtsman; stenographer; roustabout; boy or messenger.

It depends, of course, upon the size of the plant whether or not an individual is needed for each of these divisions of work, but if the plant is so small that a half dozen men can perform all of the above duties, each of them must know just what, of the above, he is required to take care of, and must do that, and not a little of everything. Lack of organization is responsible for costly errors and delays and has been a large factor in causing excess cost in more instances than would be supposed. Too often one man attempts to do all of these things, or nearly all, or is compelled to do so by not being allowed sufficient help. There are thousands of things to be thought of which need intelligent attention, in building a large plant, and even the most clever men have a limit of capacity. When this is crowded, then come those most dangerous causes of failure: "I forgot that," or "I did not have time to attend to that." To save costs this sort of thing must be eliminated.

Essentials of Construction

A plant is built of three things; material, labor, and brains. If material runs short, buy more; if there are not enough men to do the work, employ more. If there are not enough brains to attend to everything in detail, or if the brains are not organized, do not fail to observe the fact and correct it, for here lies the cause of excess cost. A plant can go ahead regularly, as planned, smoothly, without loss of time, one step after another, no blunders, nothing done over, and no alterations, but this is only possible under a perfect system of organization for efficient work. Too much cannot be said in favor of organization, as a factor in the prevention of excess cost.

Estimates seldom include any cost of preparing a yard or yards for material, or for housing and caring for stock and supplies, and any money spent for this is, therefore, an added cost. Too often, however, nothing is spent for this purpose and the result is a greatly increased cost of handling material, waste of supplies, and costly delays. The time to prepare for yards is when the site is selected. If a hillside site, the yard should be laid out during excavation, and the material moved so deposited as to form ample room for storing and handling all material with least possible amount of labor. It is quite customary for material to be delivered at the site, dumped off at the top or bottom, or scattered about over adjoining ground, at any place convenient for unloading, later necessitating high labor cost to move to place or handle. One of the best times to judge whether or not a plant is being built with intelligence and economy is just after material has been delivered; a glance is then sufficient.

When building upon a hillside, no plant is too small for it to be economical, to provide means for hoisting or lowering everything to the level at which it is to be used. This may consist of a well ballasted track for cars with hoisting engine, or only a skidway with a 'boat' and hand-winch. In

making excavations a yard can easily be leveled at each grade at one side of the site with a minimum expense of possibly a little dry-wall building, and heavy labor costs saved later during construction. (These yards should, of course, be all on the same side of the plant.) As material is delivered, all the equipment and much of the building material can be placed at once in the yard at the grade wanted. All that cannot be easily sorted at this time should be yarded at the top or bottom of the incline, according to where delivery must be made. From the time material leaves the wagon or car it should not stop moving until it is so placed that it need be moved only horizontally to its final position, or perhaps lowered a little. The boss yard man must be advised by the general foreman, or clerk of supplies, just where everything is to go. At the top or bottom yards and at important intermediate grade-level yards, provision should be made for housing or caring for all supplies in such a manner that when any piece is wanted it may be obtained with the least possible amount of labor and loss of time, and absolutely without a hunt. It costs money for a high-priced mechanic to wait for another man or to go himself to the top of the mountain or down into the cañon and hunt through a mixed mass of freight for an ingot of babbit. This certainly increases the estimated cost of babbit per pound, or the estimate of the cost of labor for the piece of work the mechanic is doing. On certain construction work where \$50,000 was the total labor cost, the records show that \$3800 was spent for moving and handling material and supplies from the point where they were delivered to where the construction gang could get at them.

Cost of Yards

Here, then, are two items of excess cost. First, failure to include the cost of yards in the estimate, afterward realizing the necessity for them and incurring additional expense. Second, failure to include this cost in the estimate and afterward incurring the expense, but spending many times that amount in handling material. The effect of an efficient organization bears very strongly on this point; more will be said about this later, when discussing the various items of equipment and material.

Most estimates will include provisions for power, air, water, shop, bunk-houses, and boarding-houses. In cases where the plant is being built close to the mine, but little allowance is made even for these items; they are checked off by noting that "such accommodations and service are already provided for at the mine." Sometimes this is true, but often the accommodations and service are entirely inadequate. For instance, it is not often that the mine bunk-house can accommodate the large number of men employed on constructive work, and in most instances the boarding-house and equipment is far too limited. Blacksmith shop built for mine work can seldom care for work of construction in addition, and besides it is not always near enough to be used with economy. The power, air, and water available at the mine are usually only just sufficient for mine requirements. All of these things must be considered carefully and after discounting exist-

ing. accommodations liberally, an allowance must be made in the estimate.

Besides these there are a number of utilities that are seldom, if ever, included in estimates, such as; ways and means of distributing power, air, water, and light to points of use during construction; provision for care, repair, and maintenance of tools and appliances; tramway or skidway equipment, maintenance and operation; cabins, mess-house, or other accommodations for the general foreman and office men who do not use the bunk-house; sanitary arrangements, fire protection, water, heat, and light service for men; watchmen, attending to men's personal wants, such as mail, etc.; saddle animals or light conveyance for use to and from railroad or town; telephone connections, when possible, with main lines, railroad, or town; caring for accumulated rubbish, its removal to points out of the way of the work, and reclaiming as much as possible for use. Many other things may be necessary, according to circumstances and conditions.

Permanent Installations

Many of these utilities may be installed permanently at the start, to serve for use later during operation of plant, but at no time are they of more use than during the construction. I recall a good illustration of the short-sighted policy of failing to provide utilities until after construction is finished. At this property the mine was two miles from the plant, and at about 2000 ft. greater elevation. The power-plant was $1\frac{1}{2}$ miles from the plant, and in the opposite direction from the mine. From the mine to the plant there was an aerial tramway and from the power-plant to plant was a large air-pipe line. During construction no telephone service was provided between these points. A record was kept of the time of men who were sent back and forth with messages, the cost of which amounted to \$425. After the plant was installed and running smoothly a complete telephone system was put in at an expense of \$240. The supplying of utilities and accommodations can easily be overdone, but necessities of this kind must be provided, and an allowance made in the original estimate to prevent any excess cost.

The including of a rock-crushing and concrete plant in an estimate is dependent upon the size of the mill. Just how large the plant must be to justify such equipment is largely due to conditions. Often a large plant is undertaken without such equipment, and in this case excess cost generally results. When such equipment is included in the estimate, the following are usually not included: good foundations for machines, "being only a temporary plant, good enough will do," with the result that the efficiency is greatly reduced and the cost of the broken rock and the concrete is correspondingly increased. Grading for buggy-ways on car tracks to site, with sufficient equipment for delivery of material to site; also for delivery of materials to concrete mixer. Care of cement, renewal and wear and tear of screens and tools, too high an allowance for subsequent use of equipment and building, etc., transmission of power, water, and light, cost of wrecking the plant when its work is finished.

The cost of all these becomes another item in excess cost.

Foundations and Retaining Walls

Usually foundations and retaining walls are figured at a certain price per cubic yard, the price varying with the class of foundation according to duty. Under certain favorable conditions, and if the estimator has had considerable experience, this should be all right, but there are many items of expense connected with this work that are usually overlooked. (The excess cost of the concrete is not to be included here.) These items are such as follow:

1. Taking out foundations and establishing centre-lines.
2. Lumber and labor necessary for making the form is always greatly under-estimated. The waste of lumber alone is an item. Also too great an allowance is generally made for lumber being used more than once.
3. Material for, and erection of buggy-runs, platforms, chutes, and staging.
4. Water service.
5. Preparing of templates.
6. Setting of hold-down bolts.
7. Leveling and finishing to grade, including surveyor's time.
8. Tearing away of buggy-runs, form, and staging.
9. Cleaning up of grade ready for the setting of the machinery and building.
10. Caring for the concrete work in inclement weather.
11. Often the base of the retaining wall is omitted in computing contents, the height being taken only to the grade-line on the drawing.
12. Failure to save and return cement bags.

In estimating in the usual way these items are supposed to be included in the cost per cubic yard, but it is not possible for this to be exact under all conditions, and the only safe way to avoid an excess cost is to consider the case, in detail.

Importance of Minor Items

The portion of the usual estimate covering equipment, is, as a rule, correct, as the figures include actual bids or prices secured from machinery dealers and manufacturers. The main chance for excess cost is in the leaving out of minor but necessary items. The most common omission in the various departments is as follows: Breaker plant; usually not much is left out here unless it is scales or weighing devices, either above the breaker, on the conveyor, above the sampler, or above the mill bins. Smaller items, such as steel for the breaker floor, lining of chutes (sometimes the chutes themselves) and an outfit. Sampling plant; this is often entirely omitted from original estimate and added later at an excess cost, owing to the necessity for rearranging the top of the plant, and installing elevators. When it is included in the estimate, the usual omissions are the frames or supports for samplers, chutes or chute linings, feeders, steel floor for sample room, fan for grinding machines, and an outfit of tools and hand appliances. Milling plant; it is difficult

to specify omissions in this part of the equipment, as no two plants are alike; hence only general items can be mentioned. Amalgamator's and battery-man's kit of tools, hose for use at batteries, sufficient valves and fittings for desired control of water at battery, especially if both clear and returned water are to be used, overhead crawl and amalgam cage (if a large mill); screws for putting down apron plates, material for apron plate stands, material for launders and launder distributors, material for gangways, platforms, and walks; clutch pulleys and belt-shifters; necessary tools and appliances; sufficient classifying capacity; sufficient fall for launders; accommodations for millmen; conveniences for making out reports, etc.; tunnels or cuts in retaining walls for belt drivers, if any.

Cyanide Plant

In the cyanide plant only general items can be mentioned, such as tools for the use of each man in this department, material for launders and launder distributors, material for gangways, platforms, walks, and steps; shifters for belts, sufficient power transmission to the many points of use, gauges, indicators, automatic registers, and solution and pulp sampling devices, report room and equipment for testing and standardizing solutions, sufficient pulp storage and settling capacity, sufficient solution storage, especially sump and gold-solution, sufficient clarifying capacity, adequate solution-circulating system to admit of universal handling of solutions, including pipe, fittings, and pumps, pipe clamps for supporting pipe-lines, sufficient grade for launders and discharges, adequate filtering capacity, accommodations for men, are some of these, also an estimate often covers the cost of cars and tracks for removing tailing from filters or vats when it is later found necessary to install conveyors for this purpose. Refinery; specifications for a refinery are nearly always complete except for such items as, scales for fluxes, vessels for fluxing, suitable arrangements for storing fluxes, acids, and gasoline, sampling devices, asbestos goods, spare burners if gasoline is used, and hose, tools, and small appliances. Power-plant; estimates for this are usually based upon the bids of dealers and are generally all right except when the specifications are at fault as regards the capacity required, which is often the case. If electric power is to be used and generated at the plant, the power-plant is generally turned over to an electrical contracting company, in which case it is usually completed according to specifications and is satisfactory. The excess cost then arises in the plant itself. Under-estimated motor capacity due to incorrect rating of machines to be driven, due to 'guessing' or 'bunching' instead of going carefully over the building and its requirements. No cost included for providing proper, clean, and ventilated places for motors. Full complement of tools, oilers, etc. Insufficient transmission; in these cases where power is purchased from a power company, in addition to these five items there is usually another larger one, resulting from insufficient transformer capacity. It often happens also that the power company will insist on placing the transformer house so far from the motors that additional capa-

city is required on account of the excessive loss in transmission.

Steam Engine Capacity

In cases where steam is used to drive the mill direct, the engine capacity is usually under-estimated on account of incorrect rating of machines driven, or low efficiency of engines, and too little allowance of power necessary to drive shafting, and for starting loads. Besides this, boiler capacity is commonly not provided in sufficient excess of engine capacity. In some climates this item can be entirely neglected, but where it is necessary it is safe to calculate the amount required as exactly as possible and then double or triple it, as there is no way of estimating heat losses in a mill building. The principal oversight in estimating the cost of a heating plant is not in the cost of the heating plant itself, but in the cost of construction of the buildings to be heated. Very little heat is required for this purpose if buildings are designed and built in such a manner as to conserve the supply. The cost of material and appliances for the distribution of the heat is usually omitted from estimates. Lighting; where lighting is done by electricity, the most common cause for excess cost is the failure to actually determine the position of light needed, so that the wiring can be exactly computed for the entire building or buildings. Dynamo and power capacity can be exactly calculated if this is done carefully. In cases where the lighting is done by oil, lamps or lanterns are usually omitted from the estimate, or, if included, are insufficient in number. When acetylene gas is used, too little attention is paid to placing each light wanted, resulting in the tearing up of piping in order to add additional lights, and generally requiring an additional generator. Machine shop; this item of cost depends upon the size of the plant constructed and upon the position of the plant with relation to any available shop. No plant is so small but what if not near a good machine shop, some kind of a shop is needed, other than the smithy, in order to avoid an excess cost on this account. The cost of any equipment of this kind is rarely included in an estimate for the installation of plant. No general specifications can be drawn for this item, as it must be determined by the style and size of the plant being built. The usual excess cost arises from leaving it out of the estimate entirely, or from failure to install the equipment at beginning of the construction.

Capacity of Machinery

In concluding these remarks upon equipment, it is necessary to emphasize that but little has been said above regarding the over-estimated capacity of appliances, which, in many cases, is one of the greatest reasons for excess cost. Nor has anything been said about the installation of unsuitable equipment or untried designs of apparatus. These are obvious to anyone, and while these notes are intended to cover only the points usually overlooked or not thought of in estimating, deal only with general cases.

Black tin output of the Aramayo Francke mines, Bolivia, in June was 248 tons.

Transportation in the Orient

The best and cheapest method of transportation in the Orient, and especially in China, is by water, and an infinite variety of boats are employed, according to the conditions to be met. They range from the sea-going junks, such as is shown in the illustration at the top of this page, which skirt the coast from port to port, down to small flat-bottomed boats rowed by a man who stands facing forward and pushes on his oars, instead of pulling on them in American fashion. Especially useful for river traffic are shallow-draft boats which use sails, float with the current, or are poled along downstream and are hauled up by tow-lines attached to the tops of tall masts. Men are universally employed to pull on the tow-line, sometimes over a dozen in tandem pulling on one boat. For travel along canals, narrow boats are used, so as to pass each other, and in order that locks can be negotiated they are frequently made in two sections which can be detached in the middle, taken through separately, and joined on the other side.

In the interior, quite other means must be employed, and in crossing the waterless deserts which separate China from Russia, camel-trains are employed. The top illustration shows a camel-cart. This is covered with felt and painted canvas, and is provided with glass windows. They make a comfortable sleeping place, but when awake the slow speed, monotony of the outlook, and cramped quarters make them rather tiresome. The camels travel twelve hours per day at the rate of $2\frac{3}{4}$ miles per hour. The next illustration below shows a tea caravan. This method of transporting tea to Russia is still in use, although railway connections across Siberia are now available. Most of the caravans now go by way of Urga to Irkutsk, where the cargo is transferred to the Trans-Siberian railway. The camel is commonly thought of as at home on the hot deserts, but in Mongolia they are chiefly used during the dry cold winter, being turned out to grass during the summer. They are much used in parts of northern China that are not desert, as they are able to carry heavier loads than mules or ponies.

A common method of transport in towns and cities is the wheelbarrow, which is of many patterns, one of the best being shown in the illustration. Heavy loads are moved on these, the centre of gravity of the load coinciding with the axle of the wheel, so that the load balances itself, and the man has only to push. To aid

him in keeping the load from tilting, the handles are made with a wide flare, and what little weight he carries is borne by the strap across the shoulders. In this way heavy loads are transported for distances of several miles. The wheels are rarely greased, and the squeak of the native wheelbarrow is a sound few 'old China hands' can forget. For moving material shorter distances, though often used for over a mile or two, the carrying pole is in universal use. This is of springy wood and is fitted

a pack on a Korean saddle, a lash-rope is put over the outside of the pack, but the balancing of the side loads and the contact of the sling-ropes with the outside ends of the saddle keeps the load in place. The Chinese pack-saddle is differently constructed, consisting of a wooden frame heavily padded beneath, and which may or may not be cinched to the animal. The pack is tied on a wooden frame which fits over the saddle, and can be easily put on or taken off without loosening the pack.

with ropes at each end by which loads may be tied, or baskets attached, in which the objects are placed.

The first of the group of illustrations on this page shows a Korean and his pack-pony. These hardy little beasts easily carry a 200-lb. load over a bad trail at a fast walk. Each pony has its own attendant, and as only stallions are used, they are kept muzzled. According to Korean practice, ponies are not allowed to lie down at night, but are tied with ropes to the roof of the stall. They are only watered at feeding time, and when working are given cooked food three times per day. Their food is chiefly beans and chopped straw or other forage placed in a trough with plenty of water. In order to enable the pony to eat the beans on the bottom of the trough and breathe at the same time, his nostrils are slit for some distance up. In slinging

This arrangement is hard to beat, except on very brushy or narrow rocky trails. The balancing of pack on the frame and the close fit of the frame to the saddle makes the use of lash-ropes unnecessary.

The illustration at the right shows a Siberian post conveyance or *tarantass*. This is a sort of bathtub slung on poles between the two axles. It is usually covered with tin on the bottom to keep out water when fording streams or when negotiating mud-holes. The occupant sits flat upon straw in the bottom and wedges himself in with his luggage. The driver has nothing much but force of habit to keep him on the vehicle, and if he is in the humor, he can generally give the passenger at least an exciting ride. There are no buckles to a Russian harness, and there are always frequent stops to tie something. No brakes are used.

The lower illustration at the left shows the method of traveling with the fast post in Mongolia. The post route between Kiaokta and Peking was established by treaty between China and Russia, some years ago, for the use of officials of either Government when on business, and for mails. The cart is pulled by Mongols on horseback who tie a pole to the cart shafts at right angles to the shafts and take the ends of the pole on their saddles. A full complement consists of eight ponies, two on each end of the pole, two in front with ropes attached to guide, and two, also with ropes, in the rear of the pole and slightly at the sides to pull back. Needless to say that with frequent changes of animals considerable speed is developed. At each stage of the journey a clean tent is erected for the traveler, and his luggage is taken ahead in a light cart and awaits at the end of each stage. Money in this part of the world consists of lump silver, and each person carries his own particular kind of scales, and pieces are chopped to fit the amount needed. The Siberian post stations are Government institutions, placed along the post-roads at distances from ten to twenty miles apart. Each station has several changes of horses, and the rate for hire is nominal. One room in each station is reserved for the use of travelers, and contains two wooden benches for beds, a table, lamp, mirror, *ikon*, wash-basin, rules and regulations, and complaint book. Prices for food and hire of horses and conveyances are fixed by schedule. On a busy road, or at times when the mail is going through, the traveler has considerable waiting to do to obtain fresh horses, but if he has a special permit, such as Government officials have, he can keep going constantly.

The illustration at the lower right shows a Chinese *shan-tze* or mule-litter. The traveler reclines on a bed of straw or felt, and the driver walks or rides behind, constantly requesting the occupant to move to the right or left to 'trim ship.'

A new slime collector, devised by R. V. Smith, is being tried at the Daly-Judge mill, Utah. It consists of a belt conveyor which allows slime to come to rest, and which is dewatered to enrich the valuable portion of the slime. After this, the product will undergo further treatment to recover the lead-silver and zinc concentrates. Only the crystalline minerals will be caught, and no attempt will be made to recover all the metal content of the slime. The overflow from the last Callow tanks and from the 'slime' ends of those Wilfley tables treating what is termed 'slimes,' is the product to be treated by the new machine.

Gold production of West African mines in June was as follows:

	Tons.	Value.	Profit.
Abosso	8049	\$ 70,000	\$15 000
Ashanti	9798	165,000	55,000
Broomassie	2800	50,000	10,000

Iron-ore shipments at Lake Superior points in June were 7,974,444 tons, making a total of 16,125,042 tons for the season, against 13,690,671 tons for the same period of 1912.

Minerals Separation, Ltd., v. James M. Hyde

*Complainants are owner and its license of United States patent No. 835120 for improvements in a process of ore concentration, issued on an application filed May 29, 1905, by said owner's grantors, Messrs. Sulman, Picard, and Ballot, of London, England, joint inventors and patentees, and this suit is for infringement of certain claims of said patent by defendant, a former employee of said owner, and by it trained in the process. The defenses are various grounds of invalidity hereinafter noted so far as of merit and seriously urged and non-infringement.

The Invention

The invention claimed, in general terms, may be said to be the discovery in March 1905, that if a very small and appropriate quantity of an oily substance, ranging around 0.02 to 0.5% of the weight of the ore be added to a pulp of water and finely pulverized ore (the slime being helpful and most easily recovered) and the whole vigorously agitated and thereby thoroughly aerated by great and excess quantities of air, the metalliferous particles are oiled and adhere in a complete envelope to or of bubbles of the air and rise to the surface of the mixture on occasion of agitation, forming a strong coherent and stable froth easily removed. The process may be aided by heat to more quickly and effectively disseminate the oily substance through the pulp and bring it into contact with the metalliferous particles, and may also be aided by a mineral acid or salt up to 1% thereof of the weight of the ore to increase the preferential affinity of the oil for metal over gangue, but not sufficient acid to cause chemical action on the metal, nor is it intended to generate gas for flotation. The patent specification is full, complete, and clear to those skilled in the art, and describes one well known apparatus of mixing vessels, spitzkasten, etc., and the operation of the process therewith.

Prior Processes

The claims are general and particular, all calling for oil and agitation to produce a froth, some defining a range or quantities of oily substance, some likewise of acid, some specifying oily substance alone, some oily substances in various combinations with heat or acid and with both. The main defense of invalidity is lack of novelty and anticipation. In reference thereto it appears from the evidence that the use of oil, air, and agitation in ore concentration, separately and in various combinations, and with other ingredients, was well known to the art prior to the discovery of the process in suit. To fully summarize the prior processes, some of them were bulk oil processes, using oil in such large quantities that in taking up the metalliferous particles in the pulp the mass thereof was yet sufficiently buoyant to float to the surface of water, the gangue sinking. Concentration being more essential for lean ores, economy is the foundation of success, so other of

*Abstract from Judge Bourquin's decision.

these processes reduced the amount of oil to a degree where it was not sufficient of itself to float the metal, and to aid therein, air, steam, or gas was injected to render the mass spongy. Another process further reduced the oil and to and around 4 to 6% in weight of the weight of the metalliferous content of the ore, the somewhat novel result being that the metalliferous particles were by the oil agglomerated into granules which sank in the water and were retained in the mixing vessel, while the gangue rose and was carried off by upcast. Some dispensed with oil and employed surface tension or skin flotation by floating off the powdered metalliferous particles on the surface of quietly flowing waters, or by injecting air, steam, or gas into the mixture of ore and water, or by generating gas therein, where bubbles attached to said particles and carried them to the surface of the water, in all the gangue sinking. Another process sought the same end by spraying the oiled metalliferous particles through air and on to water, where they remained, the gangue sinking. In some processes acid was used to generate gas *in situ* for flotation, while in others it was used solely to render more pronounced the selective attribute of oil for metal over gangue. This last feature was the discovery, so far as ore concentration is concerned, of Carrie J. Everson, of Chicago, to whom a domestic patent, embodying it, was issued in 1886. In some, heat was used to hasten the action of the oil, and some resorted to agitation.

Froment's Patents

For anticipation, defendant relies most upon Froment's patents and working description. They date from 1902 to 1903. The process thereof is one wherein the ore is carefully crushed in two operations so as to minimize slime, and is first deslimed, for that the slime is "too fine to be treated," quoting Froment. Thereupon, to a mixture of deslimed ore and water, oil and carbonate of lime (which may be limestone) are added proportionate to the weight and richness of the ore, from 1% of oil in weight of the ore, for one containing up to 5% of metal, to 3½% of oil for ore containing 50% of metal, and from about 1% of carbonate of lime in weight of the ore, 2½% in difficult cases, or more, and in like proportions to the oil for richer ore, it requiring more gas. Agitation in mixture containing two stirrers revolving in opposite directions and for a few minutes, or about 10 minutes, at about 300 revolutions per minute, the "chief point" being that all metallic particles are brought "into thorough contact with the oil," is described by Froment. The mixture is then discharged into a vat containing a perforated coil through which sulphuric acid is introduced in quantity about 10% of the carbonate of lime, and a vat therein turns slowly and about 10 to 12 revolutions per minute to prevent the ore collecting at the bottom in too compact a mass.

Steam may also be injected through said coil to assist the reaction, but it is necessary in only cold countries. The reaction of the acid generates gas, which in bubbles carry the sulphides to the surface, here skimmed or pushed into a hopper. Such thereof as fall back and sink are otherwise recovered. A large proportion of the oil may be recovered from

the concentrate in a press. Froment's patents refer to the use of gas of any kind, that the bubbles will become covered with an envelope of sulphides and rising to the surface form a kind of metallic magma, and the formation of these metallic spherules is singularly active if the gas is in a nascent state. There is little evidence of practical use of any prior processes, and no substantial evidence that any substantial commercial success has accrued to any of them, or that any of them has had any considerable continuous successful operation. Froment's process has not been in practical operation.

Comparisons of the Process

Complainants' process has, in substance, displaced some of the prior, and has firmly established itself as evidence shows many and large plants thereof, built or building, in widely separated parts of the world. Its successful operations, practically from discovery, have recovered, and largely from waste and tailing, value aggregating nearly \$9,000,000, and at a profit of nearly \$4,000,000, to the patent owner and its licensees. Looking to the evidence, and therefrom contrasting the process with complainants', Froment's requires several times the quantity of oil than does this in suit, both by examination of the patents and working description and by tests in evidence. Froment crushes the ore in two operations and deslimes it before treatment, because the slime is too fine to be treated by his process, while the process in suit needs but one crushing operation and finds slime advantageous and most easily recovered. Froment employs carbonate of lime, the process in suit does not. Froment requires acid and in greater quantity and for a different function, than does the process in suit, which latter may or may not use acid. Both may use heat, and both require agitation, Froment, agitation only to disseminate the oil, the process in suit for that purpose and also to aerate. Froment's result is by flotation by gas generated *in situ*, this in suit is by flotation by air introduced by vigorous agitation. Froment's product is like unto a magma, a spongy, pasty mass of oil and metallic particles, and more or less gas bubbles, while this in suit is a froth of oil and metallic particles and air bubbles. Froment's requires oil in such quantity that he deems it worthy of recovery from the concentrate, so far as it can be, this in suit so little oil, it disappears, is not sensible to sight or touch upon the concentrate, but only to analysis. In Froment's, it would seem that the metallic particles are floated like the basket of balloon, while in this, like the very envelope of a balloon. Froment's is costly, while this is cheap. And from the evidence, it would seem that Froment's process would fail in practical operation, while this in suit has succeeded. In Froment's, he oils the metallic particles by agitation, then, when the mixture is quiescent, generates gas therein by quick reaction, followed by immediate and direct rising of the gas bubbles to the surface in which they may come in contact with but few metallic particles. In this in suit, vigorous agitation of the mixture beats great and excess volumes of air therein, likely bringing the ultimate air bubbles into repeated contact with many metallic particles. The action of the

gas in Froment's is almost explosive in nature. He speaks of proportion of carbonate of lime to be sought as in his test tube example, the reaction may be so sudden and violent as to project the metallic particles out of the tube. Froment's gas bubbles, quick formed and quick rising, it may be, arrive at the surface with expansion still in progress. These or analogous reasons may account for Froment's magma breaking gas bubbles and fragile evanescent froth in so far as his result is like unto froth, and also may account for the process in suit's strong and lasting froth.

Definition of a Patentable Process

The differences hereinbefore set out between Froment's process and this in suit, are so obvious, numerous, radical, and, in many respects, vital, it is clear they constitute different processes. They are different in ingredients, function of some thereof, combination, manipulation, principle, and result. Their points of resemblance only serve to accentuate their difference. Broadly speaking, a process is a definite combination of new or old elements, ingredients, operations, ways, or means to produce a new, improved, or old result. Any substantial change therein, by omission to the same or better results, or by modification or substitution with different function to the same or better result, is a new and patentable process. New or substantially changed methods whereby the product is bettered, increased, cheapened, may be a new and patentable process.

In this suit the doctrine of equivalents has no application. The process in suit is so clearly new that no exhaustive discussion of facts, cases, or law is necessary to distinguish it from other processes or to demonstrate its novelty. The patentees herein discover a new, cheap, simple, practical, and useful way or process to combine oil and air and, by agitation, to float and secure the metallic contents in ore concentration.

Present v. Prior Patents

To whatever extent they drew from the prior art, as they rightfully could, they took the last and successful step. It is urged, however, that as the patent in suit does not specify exact quantities of oil and acid, but a range thereof, it describes merely an experiment not patentable. It is true, every ore presents its own problem of reduction. So while all may lend themselves to a general method, each may require some modification of the method. All skilled in the art understand this, and know that in addition to the best scientific theory they must add the light given by trial and practice. To the contention that, as in Froment's process, the agitation must entrain some air like unto that of complainants' and so the latter lacks novelty, it may be observed that if so, it was unintentional and unrecognized in that Froment had in mind only flotation by quick acting gas generated *in situ*, it aided the art none and is unimportant.

To the argument that in operating, Froment, in rightful economy and decrease of oil, and in rightful omission of carbonate of lime in treating ore containing it in sufficient quantity, his process would approximate this in suit and arrive at a like froth

and hence lack of novelty in the latter, the response is that the fact that infringement may be easy does not impeach an otherwise valid invention, and that if Froment's methods are modified until they approximate complainants' and so produce a like product, the process is no longer Froment's, but is complainants'. Upon all the evidence the Court is of the opinion the defense of lack of novelty and anticipation is not established. Another defense is that the invention was not joint. It seems the patentees were experimenting with the Cattermole granulation process. An experimenter in their employ, in obedience to their instructions, determined on by consultation between all said patentees, and to which each contributed suggestions, gradually reduced the amount of oil until the result was the peculiar froth of the process in suit. The experimenter was but the instrument through which the genius of these patentees found expression.

Conclusion and Verdict

The circumstances are sufficient to constitute these patentees joint discoverers. At any rate, it is not proven they are not. Although some of the claims in issue include elements not absolutely essential, namely, heat and acid, and in respect to which they may afford no protection, they are not invalidated by undecieving superfluous features, if heat and acid are such. The patent is valid in respect to all claims in issue. Enough appears in the evidence to compel the conclusion defendant was using complainants' process and was infringing the claims in issue as charged.

Mining Costs at the West End, Tonopah

The following figures are from the last annual report of the West End Consolidated Mining Co., and show a direct decrease of \$1.28 per ton on the previous year:

COST PER TON		
Superintendent and foreman	\$0.135	Excavating 0.027
Breaking	0.802	Assessment 0.011
Timbering	0.090	
Tramming	0.372	Total direct \$3.608
Hoist, etc.	0.200	
Ore loading	0.233	Salaries \$0.145
Ore sorting	0.366	Office 0.046
Ore sampling	0.004	Legal, etc. 0.031
Surveying	0.047	Taxes 0.012
Surface	0.135	Insurance 0.020
Assaying	0.040	Depreciation 0.067
Drayage	0.015	Automobile 0.044
Ore dump	0.045	Bullion tax 0.131
Development	0.862	Liability insurance... 0.058
Electric wiring	0.012	
Shaft-sinking	0.212	Total indirect ... \$0.554
		Total operating... \$4.162

The canning industry of the United States produces goods valued at over \$160,000,000 per year, California leading with about \$40,000,000. This will give an idea of where the great output of tin-plate is consumed.

Coal-mine fatalities in the United States during May were 195, making 1078 for the first five months of the year

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

The Psychology of Zinc

The Editor:

Sir—F. L. Clere's letter of June 9 in the *Mining and Scientific Press* of July 12 has been read with interest. Among some sage remarks on the technology of zinc smelting, remarks which show your correspondent to be a close and accurate observer, are some observations of a character quite unworthy of a writer of the standing of Mr. Clere.

Mr. Clere is, I think, quite unintentionally misleading where he states that "a rich concentrate containing between 50 and 60% of zinc must be made before the smelters will look at it." It is true that for the most part in the middle western fields such a grade is produced, but this is purely a matter of metallurgical and financial balance on the part of the mines and not from the demands of the smelters. That such is the case is shown by the fact that the ores from the Rocky Mountain districts shipped to smelting works will average considerably less than 40%. During the year 1912, ores were shipped from Colorado to Oklahoma, with a zinc content as low as 18%, and apparently both parties to the transaction were satisfied. As an evidence that the process of mining, milling, and smelting taken together are efficient, it may be mentioned that zinc ores of less than 2% zinc are being mined, milled, and smelted, at a cost of considerably less than 6c. per pound, and this without any help from silver and gold, which compares favorably with the porphyry coppers.

I can remember a time not many years ago when the lead smelters in Colorado were receiving ores containing 20 to 25% zinc, and the slag contained 8 to 10% of this hated metal. Today that condition no longer obtains, and I cannot help remembering also that it was a zinc metallurgist who contributed most to that desirable end. Let Mr. Clere cheer up, perhaps another Wetherell may arise to point a way to utilization of his 20% zinc ores of which he has such "enormous" deposits. In passing, let me remark that so far as concerns "enormous" deposits of 20% zinc, "opened by shafts and drifts," you might glance at the locality whence this communication is sent.

Notwithstanding the benighted state of the zinc metallurgists who will not follow the lead of their brethren in other branches of metallurgy, and discard furnaces and apparatus known (by Mr. Clere) to be obsolete, I may mention that during recent years many hundreds of thousands of dollars have been spent in Europe in experimentation and much valuable work is being carried on there today both on electrothermal and hydrometallurgy of zinc; and in the United States from Hartford, Connecticut, to San Francisco, California, there are, at points too numerous to mention, many experiments being carried out along the same lines.

Let not Mr. Clere despair, few of the zinc smelters maintain fences around their works, and I don't recollect ever seeing a single watch-dog in connection therewith.

The family physicians of whom we are told, are perhaps somewhat inclined toward homeopathy, for such has been their training, and I know they look with great suspicion on patent medicines and nostrums, for their experiences with the gentlemen who dispense these from the various metallurgical cart-tails have not been happy ones.

R. G. HALL.

Kansas City, Missouri, July 19.

One Reason Why Mining Languishes

The Editor:

Sir—Much has been written during the past few years in the attempt to explain the difficulty experienced by owners of mining property in interesting capital in the development of prospects or in buying their partly developed mines. The apex law; governmental bureaucratic interference with the divine right of the free American to do as he pleases, even on property he does not own; too many automobiles; unwillingness of the experienced investor to pay cash for the privilege of developing the other fellow's property—all of these, and still other reasons, are complained of by the owners of future bonanzas and their agents.

Contemporaneous with these complaints on the part of the owners, comes an equally emphatic complaint from the representatives of experienced mining capital that they can find no properties worth taking up on the terms demanded. As a matter of fact, some of the larger companies have become so discouraged that they have reduced their staffs of examining engineers within the past year or two.

Thus we find the party of the first part and the party of the second part complaining of diametrically opposite conditions; which fact seems to indicate that something is wrong with the methods used in presenting properties and propositions for consideration. In my experience, this difficulty lies in the fact that only a small percentage of the propositions presented are accompanied by an adequate convincing description of the mine itself and what it shows. It is so rare to receive a well written description by a competent engineer that is a pleasure, rather than a duty, to review such a report. The one important thing in a mine report is description of the mine. Describe the vein outcrop; then take the reader down the shaft and out through the first level, describing the vein in exact detail; describe each assay sample and tell where it was taken; then down through the stope and along the next level, etc. This sort of report is convincing to the reader and allows him to form his own opinion as to whether the mine would interest his clients. The majority of reports submitted do not contain such description, but compel the reader either to accept the opinion of some stranger to him, who wrote the report, or drop the proposition. Many badly written reports leave a lingering suspicion in the mind of the reader that, if the owner had employed a competent person to write the report and

describe the mine, the proposition might be of interest.

Here are two concrete examples to illustrate this. Recently I received a brief description of a mere prospect in northern California from a person who makes no claim of being a mining engineer. That person had visited the property, secured a tentative proposition from the owner, and had ascertained that the owner's rights to the unpatented claims were legally correct. He then described the entire proposition concisely and convincingly, quoted the owner's price to him—the option allowed ample time for development before any payments were demanded—and he stated what commission he expected in case the option should be exercised. I had a client who wanted something of this kind, so I examined it, and within five weeks the property was under bond, and development work was started. And this is merely a prospect, no ore whatever in sight.

In the other case, I have recently had occasion to struggle through thirty-odd typewritten pages of mangled and tortured English constituting an alleged report on a future bonanza, which describes everything in the neighborhood except the underground work, and is accompanied by a map which shows everything except the mines. The majority of the few samples taken are openly stated to have been taken from the high-grade streaks, and they assay well. As an example of how not to do it, this report is a gem; and yet there lingers a suspicion that if the property were properly described, and appropriate terms were offered, this might be an interesting proposition. Doubtless the owners paid a good round sum for this effusion, perhaps so much per page! The description of the geology and the lucid explanation of the ore deposition really warrants publication for the enlightenment of those of us who are obliged to struggle valiantly for a little ray of light on these profound secrets of the Great Architect.

Isn't this interesting:

"The apparent rocks are massive acid granites carrying the normal four constituents of quartz, mica, feldspar, and hornblende, with accessory minerals of value imbedded in the paste of the mass originally. This is now changed in places from segregation of the several ingredients into dikes of one or more only of the minerals, through like attracting like, from a certain intensity of magnetism being continuous for a period, this being suitable to the degree of conductivity of one of the materials in the magma. Then the magnetic current weakens, and another constituent more susceptible is effected. This would seem to account for spa dikes, hornblende dikes, and micaceous dikes, and the helping by lateral secretion to assemble the economic metals, iron, copper, etc., into the fissures. These granites are the latest volcanic molten magna that came up as plutonic or deep-seated rocks during the Upper Jurassic period in geology. Their dynamic force was violent and stupendous, and they forced their way up through all previous rocks, probably the Triassic and Paleozoic indicated by — and other peaks."

In speaking of the icefields which covered the region during the Glacial period, we get this gem:

"When icefields five thousand feet thick or more, covered the face of the land till the world tilted with its weight and shifted the equator, bringing the ice nearer the heat of the sun."

The entire report shows about the same grade of ability. Comment is superfluous, except, perhaps, to say that the report has visited the offices of various mining companies without commanding much attention.

Since starting this letter, the *Mining and Scientific Press* for June 21 has reached me. In it is W. F. Disbrow's letter on 'Vendor's Valuation of Mining Property,' which is very much to the point. By all means, Mr. Owner, read what he says and think it over. Scattered through all the important mining regions are enterprising newspapers, devoted heart and soul to boosting their region. This is right and proper, but the biggest part of their boosting consists in exaggerating the facts, and if a real investor visits the region he, too, often becomes disgusted and never wants to hear of that region again. But mostly he is used to the exaggeration and does not come. Now if the editors of those papers would take Mr. Disbrow's letter as a text and preach a few sound commercial sermons to their readers, they would be doing some boosting along new lines which would probably have a beneficial effect on the local mining industry.

Mr. Disbrow advises Mr. Owner to try and believe that the prospective purchaser is sincere, and says this, which is worth repeating: "You will find it easier to do this if you will consider *the indefinite manner in which you have arrived at the valuation of your mine*, and compare it with the systematic investigation of your purchaser." The italics are mine, and the phrase is emphasized because it seems to contain the vital point of all the discord between buyer and seller. The prospective buyer decides only after a most careful examination of the property and the operating conditions surrounding it. Even after this careful study the result is very often a failure. These failures have taught the buyer caution, and this caution is apt to be considered by the seller as a foul conspiracy to obtain his wonderful bonanza for a pittance. On the other hand, the seller's price and terms are usually based on what he would like to get for the mine, rather than on any real appraisal of the value of the property. If these premises are sound, then the solution seems to be that the cheapest and quickest way for the seller to present his proposition to the buyer is to employ a competent and disinterested engineer to report on (which means describe) his property and to advise with the owner in regard to terms and price. The expense of this is actually less than the cost and loss of time spent in peddling the proposition from office to office. The buyer must have convincing evidence, and more and more are the various mining companies demanding from sellers the reports of disinterested engineers on properties offered for sale.

Special Correspondence

BOSTON

THE FIRM OF HORNBLOWER & WEEKS CELEBRATES TWENTY-FIFTH ANNIVERSARY.—DEVELOPMENTS AT THE IRON CAP AND SUPERIOR & BOSTON MINES, ARIZONA.—CONDITIONS OF MINERS AT BUTTE AND LAKE SUPERIOR COMPARED.

The Stock Exchange house of Hornblower & Weeks recently observed its twenty-fifth anniversary. The senior member, Henry Hornblower, is president of the Boston Stock Exchange, and the junior member, John W. Weeks, is now United States Senator from Massachusetts. One of the strong members of the firm is James J. Phelan, who rose from a clerkship to an interest in the business. Mr. Phelan has a large political following, and through Mr. Weeks' activity in politics, first as Representative for several terms and now as Senator in Congress, the house gained the name of "political headquarters." Hornblower & Weeks do not specialize in mining as much as they did a number of years ago, having encountered bad weather

in their sponsorship of Bingham Consolidated. Still later there has been some tendency to criticize them a little in connection with the mining failures of the convicted broker, Stephen R. Dow, and the Sealship Oyster Co. The house maintains a mining statistical department, and offices in Chicago, Detroit, Hartford, Newport, Providence, and New York.

The Iron Cap Copper Co., of Globe, shipped fourteen carloads of ore last month to the smelter at El Paso. On account of some additional exploratory work outside of the vein on the 650-ft. level, the average grade of the ore fell somewhat below the usual shipments. Driving east on the 650-ft. level, the face of the orebody is somewhat narrower than a fortnight ago, but the ore continues to be of high grade. At present five of the six faces of the mine are in ore. The Boston management of the Iron Cap is trying hard to rehabilitate the company, which suffered so much under former management and name. The stock is occasionally traded in on the Curb here, but has not been active, and this is not looked for until the mine has been better opened.

Superior & Boston, another Globe property, is also making encouraging headway and is shipping ore found in development work to the El Paso smelter. The mine in the lower workings has suffered from extreme dampness and bad ventilation. On account of this, the management paid miners \$4 per day, 25 cents more than the other Globe mines. Conditions now have been made so much better that the normal union scale of \$3.75 per day was adopted on the first of the month.

The continuance of the Lake Superior strike has brought into comparison and controversy the difference in wage and

living conditions as between the Lake and Butte districts. By some it is claimed that the living standard at the Lake is fully 50% below that of Butte. It is said that the mining companies at the Lake exploit their workmen by renting them, at an extraordinary return upon the investment, old and cheaply built houses without any modern conveniences. It is claimed that a married man at the Lake, by denying himself and his family comforts, may save perhaps \$5 per month in the summer, but these savings are used up during the winter. Anaconda has never had a strike, and it is claimed by its friends that it uses its miners a great deal better than Calumet & Hecla. On the Lake side the contention is made that the Butte miners have to pay rents of at least \$25 per month, have to contribute an average of \$5 per month in dues to the organization and strike assessment, have to pay for their water, and submit in many ways to higher living costs than those of Lake Superior. Underground workings, on account of the cool temperature in the Lake mines, are compared favorably with the heat at depth of the Butte mines. It is pointed out that the Michigan copper miner gets his home for \$4 or \$5 per month, has no union assessments,

has his water free, and the end of the month has more money saved than the Butte miner. It is also pointed out that there is no Sunday work at the Lake, while at Butte operations go on every day in the year.

Engineers and surveyors have begun operations laying out the route of the Butte, Wisdom & Pacific railway, the subsidiary of the Boston & Montana Development Co., headed by W. R. Allen, of Butte, which will build a 100-mile road through the Big Hole basin and connect the two mining towns of French Gulch and Elkhorn.

NEW YORK

OPERATIONS OF THE INTERNATIONAL SMELTING & REFINING CO., GRANBY CONSOLIDATED, AMERICAN SMELTING & REFINING CO., AND THE GUGOENHEIM INTERESTS.—AFFAIRS OF OHIO COPPER CO.—GOLD AND SILVER SALES AND PRICES.

The International Smelting & Refining Co. is doing a big business and expects soon to blow in a fifth lead blast-furnace at Tooele, Utah. Its plants at Perth Amboy and near Chicago are running at full capacity, and when it builds a new copper smelter near Globe, Arizona, as is confidently expected, it will be an even larger factor in the smelting field. Since it has been paying 8% on its capital, and making earnings at an even greater rate, it is a profitable venture as well. The Granby Consolidated is a property which has not done so well, but which seems to have a bright outlook in its new property at Hidden Creek, British Columbia. Construction work is well advanced, and it is expected that production will begin by January next, when about \$3,600,000 will have been spent on the new property. A pleasant feature of the situation is that

costs so far have been kept well within the estimates. The dividends of the American Smelting & Refining Co. should be kept at the usual rate, even though earnings have been decreased lately, due to the shutting down of its Mexican plants by the revolution. The smelter at Aguascalientes has been steadily at work, almost without interruption, but the rest are practically all shut down, the Chihuahua plant, however, being in shape to start whenever fuel in sufficient quantity can be shipped in. With its Mexican plants operating in ragtime, the United States Department of Justice threatening to investigate it as a 'smelting trust,' the minority shareholders in the Federal Mining & Smelting Co. creating all sorts of a rumpus over smelter contracts, A. C. Beatty suing the Exploration company, and Louis Ross suing A. C. Burrage in connection with the promotion of the Chile Copper Co., this has not been an entirely happy year for the Guggenheim interests. The Cananea Consolidated has also had its troubles incident to the Mexican revolution, and is now operating at about 60% of its full capacity. This Company some time ago joined the Amalgamated family at 42 Broadway. The stock in the Greene Cananea has been reduced to less than 500,000 shares, most of the old certificates having already been exchanged.

Ohio Copper is apparently in for a thorough overhauling. M. W. Atwater having been engaged for the task. The president of the Company has given out the statement that though over 70,000 tons is being handled monthly, at a cost for mining, milling, and transportation of about 85c. per ton, the earnings are not satisfactory. The average copper content of the ore for the first five months of this year was 1.015%, so it is evident that the chief trouble must be with the recovery. It will be remembered that not long ago Col. Wall's ideas of milling practice were incorporated into the Ohio mill, but had only a brief existence. Well informed people have expressed the opinion that the property is of a good deal of value, but has suffered from too much tinkering. The balance sheet of the Company for the year ended May 31 shows assets of \$5,535,014, made up of the following items: mine and mill properties, \$4,745,789; treasury stock, \$250,000; furniture and fixtures, \$2335; unexpired fire insurance, \$792; cash, \$192,404; and accounts receivable, \$278,604. Liabilities include \$4,150,000 shares, accounts payable \$130,632. Surplus account includes profit on operations from August 1, 1912, to May 31, 1913, \$93,177 less sundry and other expenses and interest on bonds, leaving a surplus of \$8382.

Sales of gold bars by the New York Assay Office during July amounted to \$2,183,140. This does not include exports, \$5,240,882 having been sent to Europe and \$23,311 to Canada. The domestic sales indicate that gold consumption by the jewelry trade, and in other industries, is larger this year than during the past two years. While this had no direct bearing on currency and financial relations, it forms an interesting sidelight on the general state of trade. The silver market continues steady, the average for July in London having been 27 1/16d., about the same as for June, and 1d. less than the average price last year. Conditions in Mexico and China have been so uncertain that both supply and demand have been restricted. Exports from London are falling behind last year somewhat. For the period up to July 24, \$4,628,500 was exported to the East this year, compared with \$5,001,700 a year ago. While India has taken slightly more this year, China has taken a good deal less. It is doubtful whether in the five months remaining the movement will be liberal enough to equal that of 1912 when for the full calendar year \$13,872,500 was taken.

LONDON

AFFAIRS OF ORSK GOLDFIELDS, LTD.—LEAD AND ZINC DEPOSITS IN RHODESIA.—REPORT ON THE BWANA M'KUBWA COPPER MINE.

The Orsk Goldfields company provides an excellent example of 'phantom profits.' In fact, its case may be called the 'limit.' The yield of gold during 1912 was worth £36,662, and the so-called operating cost is given at £10,509. The directors subtract the latter from the former, and announce that a 'gross working profit' of £26,153 is shown. In the first flush of excitement, the shareholders naturally congratulated

themselves on the low proportion of cost to output, and looked forward with pleasurable anticipation to handling some of that surplus. But on turning to the accounts, the real result of the year's work was seen to be a loss of £3144. The directors do not tell the worst all at once, but let their clients down gently by interposing a phantom 'net' profit between the 'gross' profit and the actual 'loss.' They deduct from the gross profit the items of £3044 for winter upkeep, £10,583 for administration charges, and £5921 as royalty to the Russian government, and make a 'net' profit of £6604. They then proceed to the next step and deduct £6772 for depreciation, and £2689 for London expenses. After allowing for one or two small items in the accounts not worth specifying here, the final result is obtained, namely, the loss of £3144 on the year's operations. It is hardly necessary to make any comment on this way of presenting accounts. Your readers can make the comment themselves. The Company has a distinguished board of directors and is advised by a leading firm of mining engineers. Besides, are not the lawyers and auditors whose names appear on the front page of the report the very leaders of their respective professions?

However, let me get back to the mining operations of the Orsk Goldfields. The Company was originally formed to acquire a quartz property in the Orenburg province, South Russia, but the results were disastrous. So subsequently a tract of alluvial ground, containing gold, was acquired near Nicolaievsk in Eastern Siberia. A number of distinguished American specialists on dredging have been connected with the enterprise, namely, D'Arcy Weatherhe, C. H. Munro, and C. W. Purington. None of these gentlemen stayed long.

From time to time, during the last half-dozen years, much has been heard of the copper and lead-zinc mines in Northern Rhodesia, belonging respectively to the Bwana M'Kubwa and Rhodesia Broken Hill companies. These two Companies are subsidiaries of the Northern Copper and Rhodesia Copper companies, of which Edmund Davis is chairman, and are affiliated to the Bechuanaland Exploration company. Reports have been made persistently of the great mineral resources at Bwana M'Kubwa and Rhodesia Broken Hill, and it has been supposed that the only obstacle in the way of their commercial exploitation has been cost of transport and unamenable of the ores to simple methods of treatment. Two documents have come to hand this week that tend to knock the bottom out of all these vague stories of wealth. One is a paper read by A. E. V. Zealley, recently published in the *South African Journal of Science* describing the Rhodesia Broken Hill deposit. Mr. Zealley is an able geologist and mineralogist connected with the Geological Survey of Rhodesia. His account of the deposit is cold-blooded scientific discussion, in sharp contrast to the more comforting reports liberally distributed by those in financial control. The deposits are found in small kopjes or hillocks, 30 to 50 ft. high. The water-level is less than 20 ft. below the level of the plain, and the unaltered zone consists of hard crystalline limestone containing scattered patches and small veins of blende and galena. The kopjes consist of weathered rock containing many cavities in which are found carbonate and silicate of zinc and carbonate of lead. In the lowest part of the oxidized zone are found phosphates and vanadates of lead and zinc, the phosphorus being apparently derived from the animal remains with which many of the caves are filled.

The other document referred to is the preliminary report issued by Hooper, Speak & Co., based on S. J. Speak's recent visit of inspection to the Bwana M'Kubwa copper mine. This mine was supposed to contain 120,000 tons of oxidized ore assaying 14% copper, together with 750,000 tons of low-grade oxidized ore. It was stated also that there were indications of at least 2,500,000 tons of sulphide ore. Mr. Speak has liberally applied the 'cold douche' by reducing the high-grade figures to 50,000 tons and 12% copper. He depreciates the continuance of the water-concentration plant that was erected for the purpose of producing a concentrate rich enough to ship, for the recovery is too low, if a rich concentrate is made, and the costs of treatment and of freight are too high. The direct smelting

of the high-grade oxidized ore could not be done in a blast-furnace owing to its finely divided state. Mr. Speak recommends that development should be pushed in the low-grade orebodies below the zone of oxidation, with the object of proving some of the 'indicated' sulphide ore. Hooper, Speak & Co. are engaged at present in preparing a plan of operations for treating the sulphide and oxidized ore.

LILLOOET, BRITISH COLUMBIA

REVIVAL OF THIS OLD DISTRICT.—ORGANIZATION OF CORONATION MINES, LTD.—DEVELOPMENT OF THE LITTLE JOE.—TRANSPORT FACILITIES.

This is one of the oldest mining districts in the province, the first discovery being of placer gold on the bars of the Fraser river about 1856. Placer mining, both by sluicing and hydraulicking, was carried on until 1899, not only on the Fraser river, but also on the tributaries of the Bridge river, which empties into the Fraser a short distance above the town of Lillooet. Until 1897 the chief producers were Tyachien, Sucker, and Cadwalder creeks, and the South Fork of Bridge river, situated about 70 miles from the

SURFACE VIEW OF LITTLE JOE PROPERTY.

town of Lillooet. In 1897, prospecting for gold-bearing quartz was commenced, resulting in the discoveries of several outcrops of free-milling quartz veins on Cadwalder creek, from near its mouth, where a group of claims known as the Forty Thieves was located, to the Countless group of claims, about seven miles easterly and on the same creek.

During a visit made by W. M. Brewer to the district in 1898, he found the ground between these points all staked, and the outcrops of oxidized ore not only yielded some high-grade specimens, but so far as could be judged at that time, indicated that these outcrops were filled fissure veins possessing characteristics of permanence and continuity along the line of strike, which is, generally speaking, northeast and southwest. The district at that time, though, was quite inaccessible, the cost for freighting in supplies being about 9c. per pound, from Ashcroft on the Canadian Pacific railroad, the town of Lillooet itself being about 50 miles from that railroad. In 1901, operations were practically abandoned in the district, and from that time until 1911 there was no work done except assessment by a few 'old-timers' at Lillooet, who had faith in the country and believed that some time the town would be resurrected.

The revival was brought about early in 1911 by Arthur Noel, who may be called the father of quartz mining in northern British Columbia. He succeeded in interesting James Dunsmuir, H. B. Thompson, and B. J. Perry, of Victoria, who later purchased the Ben d'Or group, on which the first discoveries of high-grade gold-bearing quartz had been made in 1897 by Mr. Noel. These gentlemen organized the Coronation Mines, Ltd., with H. B. Thompson, president of the Company, and C. L. Copp, manager, and about July 15 the first clean-up from 188 tons of ore, yielding

\$9000, was brought to Victoria. This naturally attracted considerable attention because, although the Ben d'Or mines had not been heard of as a producer since March 1901, previous to that it had produced \$64,808 from 5520 tons of ore. The ore from which the recent clean-up was made came from the Little Joe claim and from a stope about 200 ft. lower elevation than the old workings on that claim.

From a report made by Mr. Brewer on the property in April 1901, the following is extracted, confirming the conclusions drawn then, and such have been proved to be correct by the work done during the past two years:

"The Little Joe vein has the following characteristics: a true fissure, strike north 75° east magnetic, which is the general trend of the vein where exposed across the Little Joe and Countless claims. With slight variations this vein apparently maintains continuity a distance of about seven miles, and dips 65° to the north, with a width varying from 12 in. to 3 ft., in the underground workings. The outcrop of oxidized quartz is traceable on the surface by cross-cuts at variable distances apart for a distance of 4500 ft. The hanging wall is a highly silicious rock, probably an altered gneiss, extremely well defined and unbroken the entire length of the underground workings. Foot-wall is the same as hanging wall, with similar conditions. Vein filling consists of riband quartz, talcose gouge, and some schistose rock. Oxidized ore probably extends down to a great depth."

When the present owners acquired this property, all the old workings that the above examination in 1901 described, had caved in, consequently new working openings were started, both on the Little Joe and Countless claims, which today aggregate as follows: on the Little Joe, drift No. 3, 251 ft. below the outcrop is 361 ft. in length; cross-cut No. 4, 89 ft. below No. 3 drift is 505 ft. in length, with a drift from this 500 ft. in length and carrying ore for 375 ft. This ore-shoot has been connected with the shoot which was stoped in the old workings, and the ore from it yielded in the mill about \$40 per ton in free gold. On the Countless, a cross-cut adit 545 ft. long, 275 ft. below the surface, has been driven to ore. The most easterly group of claims situated on this belt is the Countless. Traveling westerly from that, are the Ben d'Or (now known as the Coronation), Blackbird, Ida May, Lorne, Woodchuck, and Forty Thieves. Each group comprises several mineral claims and some fractions, each full claim being 1500 ft. square, and fractions of variable size.

The present means of transportation into the district are very different from those available either in 1898 or 1901, because it is possible at present to drive a wagon or even an automobile from Lytton station on the Canadian Pacific railroad to Lillooet, a distance of 48 miles, and from Lillooet to the mine, a distance of 70 miles, and owing to these improved transportation facilities, renewed interest has been taken by prospectors who this year are exploring the adjacent country. A 10-stamp mill was hauled to the Little Joe during the winter of 1898-9, at a cost approaching 18c. per pound for freight. This mill is today reported to be in excellent condition, and the ore recently treated was crushed in it by water-power furnished from Cadwalder creek, which was developed at the time the mill was erected in the summer of 1899, and is amply sufficient to drive heavier machinery than the present equipment.

PLATTEVILLE, WISCONSIN

PRODUCTION AND PRICES OF ZINC ORE IN JULY.—DEVELOPMENT AND NEW EQUIPMENT IN THE DISTRICT.

Low prices for zinc ore militated against a normal production for July, and the output for the field was 5,000,000 lb. of zinc concentrate lower than for the published reports covering the month of June. High-grade ore sold well in July on a basis ranging from \$42 to \$45 per ton for 60% ore. The bulk of the mine production, however, ranges from 30 to 55% for this field, and it is on the lower grades that the most serious inroads have been made. Thirty per cent ore brought \$16 per ton, at which figure no profit can be made, as the average Wisconsin concentrate costs this much to produce, figuring fuel and cartage; 35% sold at \$17.50 to \$18; 40% ore brought \$21.50

per ton; 45%, \$24 to \$25; and 50%, \$28 to \$30; all grades carrying the usual penalties for iron.

Car deliveries for the month were made as follows: To Mineral Point Zinc Co., 94 cars, 3490 tons; Grasselli Chemical Co., 34 cars, 1285 tons; National Separating Co., 27 cars, 1063 tons; Illinois Zinc Co., 22 cars, all high-grade separator ore, 892 tons; Empire Roaster Works, 15 cars, 553 tons; Matthiesen & Hegeler Zinc Co., 11 cars, 398 tons; Linden Zinc Co., 13 cars, 390 tons; Joplin Separating Works, 3 cars, 126 tons; a total of 219 cars, equal to 8202 tons. Shipments of lead ore were light, although prices were better maintained through the month than on zinc. The Federal Lead Co. secured four cars, 238,000 lb.; St. Louis direct, 239,160 lb.; a total of 477,160 pounds.

Heavy deliveries of iron pyrite came from the Wilkinson mine at Benton to the Grasselli Chemical Co., 3,089,240 lb.; National Separating Co., Cuba, 864,790 lb.; Linden Separating Co., 276,140 lb.; a total of 4,230,170 lb., about 2,000,000 lb. under the production for June.

The gross production of concentrate from mines during the month aggregated 13,872,390 lb., and net to smelters 10,886,800 lb. The Mineral Point Zinc Co. delivered to the smelter at De Pue, Illinois, 26 cars of roasted ores, equal to 1,884,300 lb., about half of the usual monthly deliveries.

Work in the various districts may be summarized as follows: The New Jersey Zinc Co. is planning extensive operations in the Highland district and is rigging up five power and concentrating plants. Linden reported four good ore developments on the Ross, Glanville, Gribble, and Optimo. More men are being taken on at the operating mines. Mineral Point shows activity about the works of the New Jersey Zinc Co., and the acid works will be remodeled. The Mineral Point Public Service Co., supplying electric power to mines and the industry generally, installed new machinery. Platteville witnessed a tremendous slump in local production, only two mines now producing and shipping. Benton holds up best of any 'camp' in the field, and reports almost normal production. The Fields Mining Co. reported the opening of zinc ore on new land. The orebody is 32 ft. thick. Hazel Green made its usual showing in deliveries, the ore coming from the Kennedy and Cleveland mines. A new development is being 'stripped' at the Scrabble Creek mine, owned by the Cleveland company. The Lawrence mine is producing, and a new 125-ton power and concentrating plant is now almost complete. Shullsburg shows the output of the Rodhams, Winskill, and Milwaukee-Shullsburg mines only. Galena is producing very little ore. A new paint factory is being established at this point by Edward T. Goldthorpe, formerly superintendent of the Skene mine at Elizabeth. Four new shafts requiring equipment are complete and in ore in the Mifflin district. Montfort has one live producer in the O. P. David, while Dodgeville has one in the Lucky Five.

SPOKANE, WASHINGTON

MINING AND MILLING IN THE REPUBLIC DISTRICT.—DEVELOPMENT AND MILLS BEING ERRECTED IN THE CHEWELAH, NORTHPORT, AND ORIENT DISTRICTS.

The Mountain Lion mine and mill, in the Republic district, was examined by J. Lorn McDougall, in the interest of the McLaren Bros., or estate, of Ottawa, Canada. The mill has since been examined by local engineers for the purpose of ascertaining the cost of remodeling it for treatment of the Mountain Lion ore by the latest method of cyanidation practised in the 'camp.' A large tonnage of \$7 to \$8 ore has been blocked out in the mine.

Milling practice at Republic is apparently still in the experimental stage, judging from the absolute inactivity of the North Washington Power & Reduction Co.'s mill and recent break-downs, and substitution of new machinery in that of the San Poil Consolidated. Here a Williams hammer-mill of heavier construction, and a new 350-hp. engine have replaced lighter machinery, and the rated capacity of 125 tons per day has not yet been attained. The present weekly output of bullion is reported at \$4000 to \$6000, from about 735 tons of ore treated.

The Knob Hill company has declared a dividend for July of \$5000, being $\frac{1}{2}$ c. per share on its capital stock. This Company may open its lower levels.

The Republic Mines Corporation is employing 30 men on the 400, 500, and 700-ft. levels of the Surprise mine, stopping south of the shaft from the 500 to the 400 and north on the 500-ft. level. The present production is from 125 to 150 tons per month, and the ore assays from \$15 to \$20 per ton. This Company, during July, shipped 1358 tons of ore to the smelters. In the northern part of Ferry county the Shawnee company is contemplating a resumption of work, and the British Columbia Copper Co. is about to resume work on the Lone Star and Washington mines. J. L. Harper has taken a bond on the Faithful-Surprise mine, the consideration being given at \$60,000. At Meteor, the most southerly mining town in the county, the Gwinn Mining Co. is installing a concentrator and erecting a dam on Hall creek to generate electric power for its mine and mill. The Gwinn ore has a value of about \$16 per ton in gold, silver, copper, and lead.

The Chewelah district of Stevens county is at present the most active. The Copper King company has received from the Granby smelter at Grand Forks, British Columbia,

MAP OF WASHINGTON.

returns from two cars of ore amounting to 41.6 oz. silver per ton and 8.65% copper, with a net value of about \$40 per ton.

The United Copper Co. has driven its lower adit about 2500 ft. and has gained about 1000 ft. depth. The shaft is down 600 ft. and has cut some stringers of high-grade ore unexpectedly. On the 500-ft. level, a drift on the vein has exposed the best grade of ore ever cut in the mine. The present shipments average 26 tons of crude ore and five to six tons of concentrate per day. The stockholders of the Company are holding the value of the stock on a basis of \$2,500,000 for the mine. The main adit on the Aurora mine is in about 1000 ft., and has attained a depth of 547 ft. at the face. It has cut two veins; the first, near the portal, is 40 ft. wide, with ore assaying up to \$20 per ton. The other was cut at 470 ft. from the portal and is about 30 ft. wide, of which 10 ft. assays about \$20 per ton. The adit is intended to be driven about 5100 ft. in all, and may cut a third vein soon, if indications are to be relied upon. The Standard Chewelah company has installed an engine and a 5-drill air-compressor in addition to a hoist, boiler, and other equipment.

In the Northport district, G. H. Safford, of Spokane, has leased the ore dump of the Paragon mine and is concentrating the ore by first passing it over a grizzly, separating the coarse and washing the fine through riffled sluice-boxes and finally jigging. The principal metal content is copper.

In the Orient district the White Elephant company is erecting a concentrating plant, has installed a sawmill, and is cutting lumber on the ground. The Galena Hill company has finished sinking to the 200 and will sink to the 400-ft. level. The vein will be cross-cut on the 200, 300, and 400-ft. levels. The vein is four to seven feet wide and has a dip of 35 to 40 degrees.

General Mining News

ALASKA

NOME

Reports from every district on Seward Peninsula complain of want of water for placer mining. The total rainfall so far this summer is only one inch, the lowest in 14 years. The snowfall last winter was also light, and as a result all gold-mining operations except a few dredging projects have been suspended.

VALDEZ

Later reports from reliable men in Alaska all tend to confirm the promising character of the new placer district at Sushanna, as detailed in our special correspondence last week.

ARIZONA

GILA COUNTY

(Special Correspondence.)—At the Inspiration Consolidated company's millsite the first concrete was poured into the forms on August 11. The grading gang finished its work on August 15. The concrete mixers at the millsite are set upon platforms and the sand, cement, and crushed rock carried to them, already mixed, by conveyor belts, the machines merely mixing the material with the water and discharging it into long wooden troughs or launders, which will convey the concrete downward to the successive walls as they are built one below the other. The concrete now being poured at the ore-bin foundations near the hoisting shafts in Webster gulch is being supplied from a flat-car, upon which the mixer is mounted. Launder leading out from each side of the car make it possible to fill forms on each side of the car as it moves along the track. The quarry, west of the millsite, is supplying about 80 cu. yd. of rock per day for the ore-bin construction and about an equal amount for the beginning of the mill building. As work at the latter progresses, the quarry will be opened and its output increased. Cement is arriving at the rate of a carload per day.

Ore will be removed from the Kingdon shaft of the Old Dominion, while 'A' shaft is being prepared for skip hoisting. Work on the concentrating plant is progressing rapidly. At the Copper Hill shaft of the Arizona Commercial, development work is being increased. The raise recently finished between the No. 8 and 6 levels revealed considerable sulphide, and that section of the mine will be thoroughly explored to ascertain the extent of the ore.

Development in the Miami mine covered 5600 ft., exclusive of reopening the ground in the northwest section of the orebody. R. B. Canby is erecting an experimental leaching plant for New Keystone ores at the Miami mill. The Iron Cap mine is being worked at six faces, of which five are in good copper ore. Fourteen carloads of ore were shipped to the El Paso smelter during July, although the average was not much above 8% because of the semi-exploratory nature of the work on the 650-ft. level, where the widening of the vein occurred. During the present month the ore shipped will be of higher grade.

Miami, August 6.

Definite information has been received at Globe that the International Smelting & Refining Co. will build a large smelting plant at that place. It will consist of reverberatory furnaces and converters.

A smelter is to be built in the vicinity of Christmas with sufficient capacity to handle the ore immediately in the neighborhood, and it is also stated that the London & Arizona Mining Co. will have its ore treated at this smelter.

GREENLEE COUNTY

It was expected that the first roasting furnace of the new plant of the Arizona Copper Co., at Clifton, would be started on August 15, and a week later a blast-furnace will be blown in. Ore has already been hauled to the smelter site. L. D. Ricketts will take personal charge of the plant for about three months. At the old smelter, one furnace will continue work while the new one is getting

into its stride. At the mine, the Coronado tunnel will be finished in a week or so, a total length of 6310 ft. Its function is for transport of ore from the Coronado and other sections of the Company's mines to No. 6 concentrator at Morenci. A large addition to this plant will be completed by September 1. A sulphuric acid plant is to be added to the new smelter with 50-ton daily capacity.

MARICOPA COUNTY

The Vulture mine, near Wickenburg, is now producing between \$80,000 and \$90,000 of gold per month, and has several years ore supply blocked out. The 20-stamp mill and cyanide plant treats 100 tons of ore per day, mostly from the 1000-ft. level.

MOHAVE COUNTY

It is reported that the Gold Reed Mining Co. has cut the vein at a depth of 250 ft. and at that point it is large, in fact one of the big veins of the Tom Reed district. The ore is said to have a high average value. The property has been in charge of H. H. Shuck since the commencement of work on the company account.

The first drill-hole of the Kingman Copper Mining & Milling Co. was finished last week at about 500 ft. depth. Assays gave satisfactory copper content. The Copper Giant shaft is down 250 ft., and drifts have opened 9 and 7 ft. of ore, respectively, carrying 8% copper and some gold.

YAVAPAI COUNTY

(Special Correspondence.)—The Block Mines Co. has taken over the Billy Boy and Christmas group of mines and claims, situated on the Hassayampa river northwest of Wickenburg. This is the result of the reorganization of the Company which was recently perfected. Among the officers chosen was Ed. Block, who will be secretary-treasurer, and as soon as the official proceedings are satisfied by the New York directors, active development will be begun, which should be within the next thirty days. Mr. Block, the new secretary-treasurer, has been the owner of these two groups of claims for a number of years, and on the splendid developments the operation of the properties was determined upon on a recent trip east by Mr. Block. The Binghamton mine, at Stoddard, has recently exposed large bodies of copper sulphide ores, and production is being made as fast as possible. At the Queen mine, in this district, driving is being done on the lower levels and gold ore is in sight in all the workings.

Prescott, August 7.

A Humphrey revolving-hammer type mill, built by the Arizona Mine Supply Co., is being installed at the Hopper mine. Good lead and zinc ore is being opened in the Ruth mine, six miles south of Prescott. The Arkansas & Arizona Copper Co., whose property is near Jerome, will connect the main shaft with the Verde Tunnel & Smelter railroad. The shaft is being 'raised' from the 1400-ft. level. The Monte Cristo, Nelson, Copper Queen, Bluebell, and Swastika mines are all developing in a promising way.

CALIFORNIA

BUTTE COUNTY

The total returns from Oroville for the current financial year to May 31 show 3,461,375 cu. yd. dredged, yielding estimated gross returns of \$1,570,000. There are now three dredges in operation.

A nugget weighing 9 oz. was discovered in the Mineral Slide mine, near Magalia, on August 2, besides \$80 of coarse gold. A cross-cut is being driven through the property, and is in 400 ft. Rich ore has been opened.

INYO COUNTY

Work was stopped at the Bishop Creek mine and mill on August 4, on account of the financial condition of the company, but Gaylord Wilshire hopes to resume within 60 days. The mine and equipment are in good order. A good deal of development was done and a modern stamp-mill was completed this year.

KERN COUNTY

No. 10 well of the Standard Oil Co. is keeping up a production of 20,000 to 25,000 bbl. of oil per day. The oil tests 26 gravity, and none of the yield is being lost.

No. 2 well of the Pacific Crude Oil Co. is yielding 1100 bbl. per day. No. 4 of the California Counties Co. is down nearly 3000 ft. and cable tools are being used to finish the well. The Lakeview Oil Co. reports that the No. 12 well on section 25, 12-24, which was started on August 7 after the new Union rotary had been completed and the disk bits had been received, is down 300 ft. This new well will be rushed to completion and finished at the earliest possible date. All of the latest appliances for

Co. has been operating a 7-cu. ft. bucket-elevator dredge in the Clear Creek district for several years and recently acquired extensive placer holdings at Gas Point. Operations have been resumed at the Kimberly mines of the Balaklala Copper Co. with a small force of men. James Doyle, formerly in charge of underground work at the Midas mine, has been placed in charge of the Kimberly properties. The Mammoth Copper Co. is installing a new Ingersoll-Rand compressor at the Stowell copper mine.

FILLING AN OIL RESERVOIR, M'KITTRICK FIELD.

drilling are included in the rig. The new Molitor rotary disk bits are being substituted for the regular fishtail bits more commonly used. Other time-saving devices are also being used wherever it is possible.

An interesting bulletin has been published by the United States Bureau of Mines, on 'The Prevention of Waste of Oil and Gas from Flowing Wells in California,' by J. M. Pollard, Ralph Arnold, and V. R. Garfias. This is Technical Paper 42.

PLACER COUNTY

The Iowa Hill district asbestos and magnesite properties have been inspected by S. M. Sprague, of the Placer County Properties Co., and Sacramento people. The Progressive Mining Co., composed of Ohio people, is to treat the tailing of the old hydraulic claims here. A new machine of 500-cu. yd. capacity is being used which operates as follows: The gravel is passed through a revolving cylinder of ½-in. steel with a screen which separates the cobbles and coarse from the finer gravel, and the latter drops through a hopper onto a series of riffles 14 ft. long with an 18% fall, and the gold is washed free with the water passing over the riffles. The water, after leaving the riffles, is caught by a rapidly revolving wheel and forced back through a tank to the head of the riffles, where it is used again. The washed dirt and sand is caught in buckets attached to an endless chain and carried to the waste dump. The process of cleaning up is the same as was used by the placer miners on river bars. The machine was started on the tailing of the old Bumpus hydraulic mine in Indian cañon, and the gravel showed a value of 25c. per cubic yard, which is considered margin enough to return a good profit.

SHASTA COUNTY

(Special Correspondence.)—A. W. Field and associates are converting the municipal rock-crushing plant into a temporary smelter, and expect to make the first fume-control test at an early date. Ore running 30 to 50% sulphur will be used in the experiments. The process is based on refrigeration, and several laboratory experiments are said to have been successful. The Shasta Dredging Co. is negotiating for options on the Saeltzer, Peterson, Jones, Gibson, and other ranches below Redding, and will examine them for dredging purposes. The tracts were recently tested by the Oro Water, Light & Power Co., but the option of this Company was not exercised. The Shasta Dredging

Co. has been operating a 7-cu. ft. bucket-elevator dredge in the Clear Creek district for several years and recently acquired extensive placer holdings at Gas Point. Operations have been resumed at the Kimberly mines of the Balaklala Copper Co. with a small force of men. James Doyle, formerly in charge of underground work at the Midas mine, has been placed in charge of the Kimberly properties. The Mammoth Copper Co. is installing a new Ingersoll-Rand compressor at the Stowell copper mine. The long adit is reported to have cut a promising copper-bearing deposit. A tube-mill and Merrill precipitating press are being installed in the cyanide plant of the Midas Mining Co. at Harrison Gulch. Approximately 60,000 tons of tailing assaying \$7 per ton is said to be available. Repairs to the plant of the Gambrinus mine have been completed and driving for the main vein has been resumed. The Mt. Bally Gold Mining Co. is reopening the old shaft workings and a depth of 60 ft. has been gained, but work is proceeding slowly because of a heavy inflow of water.

Redding, August 4.

SIERRA COUNTY

At the Alaska mine, at Pike City, 65 men are employed, and the 40-stamp mill is working full time on ore from No. 4 and 5 levels. The letting of blocks to lessees is gradually being discontinued. George St. John has retired from the management, and his place is temporarily filled by W. S. Schuyler, of the Sierra Alaska Gold Mining & Milling Co. R. C. Turner has been appointed consulting engineer.

COLORADO

EAGLE COUNTY

Reports from Eagle are to the effect that the Lady Belle remains the only claim in the Brush Creek district which is shipping ore, or that has ore in place. Several fair-looking prospects have been opened on Horse mountain, but the extension of the Lady Belle has not yet been found. During the latter part of the week ore was found in the North Dakota claim, Brush creek, which gives assays of 95 oz. silver, 12.8% copper, and 7 oz. silver and 1% copper per ton. The claim is situated about 1000 ft. south of the Lady Belle, higher up the mountain and toward the Salt Creek side, and the formation is the same, Dakota sandstone. The vein is 4 ft. wide and the adit is in about 40 ft. It is claimed by the lessees that this is the extension of the Lady Belle vein.

LAKE COUNTY (LEADVILLE)

The Arkansas Valley smelter is now running five furnaces in full blast and treating a large tonnage of ore, indicating that the district is in a healthy condition.

The Colorado Power Co. is installing two hoists at the New Monarch mine, and has completed the transmission-line to the Mt. Champion, Lackawanna gulch. Old producers at the head of Iowa gulch are to be worked again. Interest in Lackawanna and Half-Moon gulches continues to be the leading topic of conversation at Leadville, and both districts are active. The usual amount of work is being done by lessees in the district.

TELLER COUNTY (CRIPPLE CREEK)

During July 58 cars, equal to 1500 tons, of ore was shipped from the Isabella mine. E. J. Fackerell, a lessee, is at present developing a new ore-shoot, opened by him on No. 4 vein. The drift driven north and south has already proved the shoot for the distance of 30 ft., and the ore broken fully 3½ ft. wide, as exposed in both headings, is worth from \$40 to \$80 per ton. Great activity is evident on the properties of the Stratton estate, and there

are at present 32 leases in operation and 10 prospecting permits. One hundred cars of ore, equal to 2000 tons, were shipped from the main shaft and leased properties of the Vindicator Consolidated Gold Mining Co. during July.

THE SAN JUAN

Ore shipments from Ouray in July totaled 1538 tons, of which the Camp Bird supplied 565, Wanakah 556, Atlas 177, and Revenue 65 tons. Martin J. Heller is at Silverton looking after his interest in the Buffalo Boy property of the Continental Mining Co., and to assist in the pending litigation as outlined in the *Mining and Scientific Press* of July 19.

IDAHO

BONNER COUNTY

According to Robert N. Bell, inspector of mines, this county's mines are developing satisfactorily, the lead-silver orebodies being opened sufficiently to predict that the county will soon rank in output with some of the older mineral districts. The Idaho-Continental, which has been mentioned in these columns several times, is the most important property.

SHOSHONE COUNTY

Instead of constructing an aerial tramway between its mine and mill, the National Copper Mining Co. will install an electric railroad system. This line will be about two miles long. Between 50 and 60 men are employed on mill foundation and flumes for water and power purposes. Charles McKinnis is general manager.

MICHIGAN

Houghton County

(Special Correspondence.)—The Quincy company is installing a new hoist at the Mesnard shaft, No. 8. This work will occupy several weeks. When the work is completed, the Mesnard will then be in position to contribute more largely to the daily 'rock' output of the Quincy mine. At the lower openings of the Mesnard shaft the Pewabic lode assumes physical characteristics which are quite unusual and quite different from any other local showings. The lode, instead of being wide and badly broken, is actually split into as many as two or three and sometimes four different lodes, each with distinct foot and hanging walls. These little lodes average four or five feet wide, but between the walls they are rich in copper. A different system of mining must necessarily be used to obtain good results, because it is necessary to mine the lode rock with as little waste as possible.

The Franklin company is prospecting to open the Allouez conglomerate at a depth of 3200 ft. A cross-cut from the Pewabic lode is being run a distance of some 500 ft. to cut the Allouez. This formation formerly was operated to good advantage on the Franklin property, but at a depth of 2300 ft. it 'petered out' and became so thin and poor that it was considered worthless. The development of the Grand Portage lode at the Isle Royale property continues to be quite the most encouraging bit of news at this mine. This formation first was cut by long laterals from No. 2 shaft. The character of the ground, from the first, was good, and as it has developed, the improvement has been noticeable. During the past few months the Grand Portage formation has been furnishing the Isle Royale with a fair tonnage regularly.

Houghton, July 30.

MISSOURI

St. Francois County

By a large majority, the lead miners of this county, numbering more than 4000, on August 5 voted to go out on strike, enforcing their demands for a raise in wages of 50c. per day. The executive committee of the Western Federation of Miners met on the following day to decide when the strike order shall become effective, which will probably be within a week. The companies have prepared to shut down.

MONTANA

Flathead County

The South Fork & Kalispell Copper Co., capitalized at

1,000,000 shares at \$1 each, was incorporated last week at Kalispell, to develop a group of four claims in Silver basin, eight miles from Essex, a station on the Great Northern railway.

MADISON COUNTY

An interesting suit involving extralateral rights on veins was decided at Virginia City last week. The case was that of Charles F. Simon, owner of the Missouri lode claim, and John D. Hatfield and others, owners of the Tucker lode claim. Both properties are in the Washington mining district, 15 miles from Virginia City, at an altitude of 9500 ft. Eminent counsel was employed by both parties, and elaborate maps and models were used as evidence. The plaintiff claimed the older location and alleged a side-line crossing of the Tucker apex, and consequent extralateral right to the east beneath the area between the plane of its north end-line, and a parallel plane through the point of crossing. Considerable high-grade ore was found here by the Hatfield adits. The latter people denied that the vein crossed the north end-line of the Missouri claim.

The ore-shoot is a remarkable one, lying in the bands of a granitic gneiss and almost against its contact with a sill of andesitic porphyry which conforms to the gneiss bedding, dipping to the north and east. The ore is in some places 8 ft. wide and carries gold to the extent of \$100 per ton. Testimony was introduced by the plaintiff's witness to the effect that the apex was established in several cross-cuts and adits lying to the north and west of the Tucker workings, and that it crossed the end-line of the Missouri claim in cross-cut No. 4 near its intersection with the west end-line of the Tucker claim. The result of the trial was its settlement out of court by the purchase of both claims by Mr. Ellings of Virginia City.

SILVERBOW COUNTY

The Davis-Daly made a profit of \$6000 in July from shipments of about 250 tons per day. One hundred and eighty men are employed. The Company is diamond-drilling at the Colorado section. In the old Fisher stopes the orebody is 7 ft. wide, averaging 4% copper. Generally the position is encouraging.

NEVADA

ESMERALDA COUNTY

The 10-stamp mill of the Pioneer Consolidated Mines Co. was to be started on August 14. There is a two years' ore supply in the mine above the 265-ft. level, with an average of \$11 per ton. Rich ore has been shipped amounting to \$420,000. It is estimated that 60% of the gold in the ore will be recovered by amalgamation, and 30% by the cyanide process. The ore is trammed a distance of 100 ft. from the collar of the shaft to the storage bin and from the bin gates it passes over a grizzly to the 7 by 10-in. crusher, thence dropping into a storage bin. From this bin the ore is fed into the 10-stamp battery by suspended feeders. The stamps are 1050 lb. weight and drop 5 in., 100 drops per minute. The crushed ore then passes through a 20-mesh screen and flows over silver-plated amalgamating plates, going thence to the Pearce amalgamators, where the float gold is saved. The pulp then goes to the spitzkasten, from which the sand flows directly into the vats, the first being 21 ft. diam. and 5 ft. deep. There are three of these leaching vats and 14 vats in all, of different sizes. The slime flows to settling vats that are directly over the leaching vats, three in number, and these are connected to a vacuum pump, the cyanide solution flowing through a water seal. Precipitation is by means of zinc shaving. The Nevada-California Power Co. will supply the necessary electric power.

MINERAL COUNTY

Reports from Coaldale, 22 miles south of Mina on the Tonopah & Goldfield railroad, state that the properties there will be able to soon supply plenty of coal of first-class grade. A diamond-drill has been operating for some time under H. A. Danus and associates, and down to 400 ft., three seams of coal, two being 4 and 6 ft. thick, respectively, were cut. A shaft will now be sunk.

NYE COUNTY

During the week ended August 9, eleven mines at Tonopah produced 12,560 tons of ore worth \$290,810, and during the first half of the year the total was 279,491 tons valued at \$5,608,580. This is an increase of 57,991 tons and \$977,780 in value over the same period last year. There are five more producers on the list this term. During the past week the east drift on No. 14 level of the Belmont was in good ore; the West End started sinking on the vein to the 700-ft. level; the Tonopah Extension started sinking a winze on the Murray vein; at the Halifax-Tonopah, the 1000-ft. south drift cut a new east and west vein in trachyte formation; and the MacNamara opened good ore on the 700-ft. level.

STOREY COUNTY

At the Comstock, the Ophir company reports a satisfactory week. In a raise above the 2500-ft. level, 136 tons of \$31 ore was mined, and 253 tons of second-class ore was sent to the Kinkead mill. The Mexican mill treated 597 tons of ore from the Monte Cristo claim, averaging \$8.14 per ton, with 90% extraction. The usual work was done at the Sierra Nevada 2500-ft. level, Crown Point, 1300-ft. level of the Belcher, Yellow Jacket, and the C. & C. pumping shaft, where all pumps worked satisfactorily.

WHITE PINE COUNTY

On August 3, the 10-stamp mill of the Amalgamated Nevada Mines & Power Co., at San Pedro, near Black Horse, was destroyed by fire. Damages total \$45,000, of which \$9000 or \$10,000 is covered by insurance. The plant has been idle for some time pending adjustment of finances, but at the time of the fire was running on custom ore. The directors of the Copper Mines Co. are expected to make an inspection of the property in the near future. It is stated that churn-drills and steam-shovels will be employed in development.

OREGON

Greater interest is being taken in mining in eastern Oregon, according to Fred R. Mellis, in the *Eastern Oregon Mining Journal*, and the following notes deal with the more important properties. At the Rainbow in Baker county, 18 miles from the railroad at Durkee, the country rock is a contact deposit of limestone. The mine is opened to 500 ft. by four levels from a two-compartment shaft. The vein is of a good width and averages \$10 to \$15 per ton. The stamp-mill treats from 75 to 90 tons per day, the monthly output being about \$30,000. A. P. Anderson is general manager. The Columbia is six miles from Sumpter, and consists of six claims with water and timber rights. There is 100,000 tons of ore opened, and the ore is treated by the 20-stamp mill and cyanide plant. The annual yield is about \$250,000, and since 1896 the total is \$3,500,000. Frank S. Baillie is in charge. At the Cornucopia there are 60 men employed, and ore reserves amount to 60,000 tons of \$16 ore. Recent improvements to the property cost \$100,000. The monthly yield is \$23,000. Robert M. Betts is manager. The Powder River Dredging Co. is busy, and its dredge is producing between \$30,000 and \$50,000 per month. Everything is driven by electric power. R. W. Derby is general manager. In Grant county, the Ben Harrison group consists of 10 claims, the principal ones being developed to 600 ft. depth. The vein is 75 in. wide, assaying \$17 per ton on the 500-ft. level. Rich antimonial silver ore has also been developed. Reserves total 100,000 tons. The property is well equipped with an air-compressor and machine-drills, 20-stamp mill, tube-mill, 16 concentrating and 4 roughing tables, revolving screen, Dorr classifiers, Callow tanks, and cyanide plant. The present output is \$30,000 per month. W. C. Fellows is in charge. The Humboldt is in Malheur county, 20 miles southwest of Durkee, in the Morman basin. At one time this was a large placer district. The Humboldt is developed to 400 ft. depth. The quartz ore occurs as lenses in a contact between trachyte and diorite, and averages \$7 to \$30 per ton. The 10-stamp mill and tables produce about \$10,000 per month. John Arthur is general manager. At the Highland, 14 miles from Haines, 50 men are employed, and the output is from \$10,000 to \$15,000 per month. The property can be worked

by adits to a depth of 2000 ft., and 60,000 tons of \$10 to \$18 sulphide ore is blocked out. The mill consists of rolls, jigs, Hardinge mill, Callow screens, and Deister tables, all driven by motors. Ten tons of concentrate is produced daily. Robert R. McGanghey is superintendent. The Pacific Lime & Gypsum Co., five miles from Huntington, in Baker county, has its new plant in operation, employing 75 men and producing three to four cars of lime and plaster per day. Power used totals 450 hp., supplied by the Idaho-Oregon Light & Power Co. The Ibex, in Baker county, 10 miles from Sumpter, has an adit in 3249 ft., with veins averaging 6 ft. wide. Over 100,000 tons of ore has been opened, and the mine is well equipped. The ore will probably be treated by the cyanide process. David Ross is manager. The Boulder Creek placers, near Cornucopia, are being equipped for a larger yield, while the North Fork placers, in Grant county, have 300 acres, with an 80-ft. face,

MAP OF OREGON.

which is being sluiced under 130-lb. pressure. Results are satisfactory. Other interesting properties in Baker county are the Mammoth, Mayflower, Virtue, Gem, Bonanza, North Pole, Red, White & Blue, Red Boy, Golconda, Balsley Elkhorn, Maxwell, Blue Mud, Inter-Mountain, Magnolia, and Morris.

UTAH

JUAB COUNTY

On the 1000-ft. level of the Tintic Standard, the drift is following the east and west break, with some good ore in the face. At the Grand Central, the daily output is 100 tons, and a good percentage of ore is being mined on the 2300-ft. level. A large orebody is being opened on the 700-ft. level of the Gold Chain. It carries copper, silver, and gold.

SALT LAKE COUNTY

A strike for higher wages at the Midvale concentrator of the United States Smelting, Refining & Mining Co. was started in the charge department on August 12. The men demand an increase in pay of 25 cents per day. G. W. Meintz, the general manager, stated only about 20 men had actually quit work. The strikers, however, claim a larger number have quit and say that practically all of the 500 employees will walk out unless their demands are granted.

MEXICO

SONORA

The Cananea smelter will continue to smelt Miami concentrate under a new contract.

TEPIC

The Mexican Searchers, Ltd., of London, which took over an option on the Pinavete mines in the Jora district of Tepic late in 1911, has surrendered the option and is withdrawing from the field. The general situation in Mexico is responsible for the action. Chicago people control these properties, and the English company has done over 1000 metres of development.

Schools and Societies

The LAKE SUPERIOR MINING INSTITUTE is holding its eighteenth annual meeting at Ishpeming, Mesabi range, Michigan, from August 26 to 30. There will be several excursions and interesting papers read.

With a new laboratory, the building of which has cost over \$30,000 and the equipment of which will cost \$40,000 additional, STANFORD UNIVERSITY is now able to offer to engineering students as complete and practical a course in hydraulics and testing of materials as any technical school west of Chicago.

The ILLUMINATING ENGINEERING SOCIETY will hold its seventh annual convention at Pittsburgh on September 22 to 26. The Papers Committee announces that ten additional papers will be read, and probably seven others will be presented, besides a lecture on 'The Development of Alternating Current Luminous Arc Lamp,' by Charles Proteus Steinmetz.

The KALGOORLIE SCHOOL OF MINES, Western Australia, Syllabus for 1913 contains much interesting information in its 91 pages of illustrated matter. There are 14 on the teaching staff, including five laboratory assistants. The third term begins on August 25. The school includes chemical, assaying, physics, and engineering laboratories; also the usual class rooms for mining, geology, and other subjects; while the engineering department is equipped with a gas engine, steam engine, fitting shops etc. Mining and geology students are given field work. Certificates, diplomas, and scholarships are offered, and there are openings at Western Australian mines for certain students. A full course of lectures may be taken for £5 5s. per term.

The UNIVERSITY OF NEVADA, at Reno, Register states that the first semester of 1913-14 will start on September 2. Affiliated organizations are the State Mining Laboratory, a laboratory at the Mackay School of Mines, Reno, for examination of material suspected to contain potash, State Hygienic Laboratory, Laboratory for Pure Food and Drugs, Laboratory for Weights and Measures, and the Agricultural Experiment Station. Entrance to University Schools is by examination, but a graduate of an accredited school need not sit for this examination. Reduced railroad rates are allowed to students traveling to and from the University. Board and room is obtainable at reasonable rates. A liberal estimate of necessary expenses, exclusive of clothing and traveling, is \$397. The University consists of many well equipped buildings and good scholarships are offered.

The twenty-fourth general meeting of the AMERICAN ELECTROCHEMICAL SOCIETY will be held at Denver, on September 9, 10, and 11. The first day will be devoted to reading and discussion of papers, various trips, and a smoker. On the next day a car will be taken for Boulder, and a session for papers will be held at the University of Colorado. After lunch automobiles will be taken up Boulder cañon to the power-plant of the Central Colorado Power Co., at the entrance to the Boulder tungsten district. On September 11, a session will be held in the evening for the reading and discussion of papers at the School of Mines at Golden. For the afternoon various visits are being arranged. An informal picnic dinner will also be held on Lookout mountain, just west of Denver, behind Golden. Various visits are being arranged to places of great natural beauty, as well as to chemical and metallurgical works. J. W. Richards, Lehigh University, South Bethlehem, Pennsylvania, is the secretary of the society.

The UNITED STATES CIVIL SERVICE COMMISSION announces an open competitive examination for assistant curator in the Division of Mineralogy and Petrology in the National Museum, Washington, D. C. The salary will be \$1800 per annum. The subjects of examination are crystallographic mineralogy, descriptive mineralogy, petrology, chemistry, education, training, experience, and fitness.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

D. J. ROBERTS is visiting Hayden, Arizona.
HENRY L. HOLLIS was in New York last week.
F. G. JANNEY has returned from Juneau, Alaska.
DAVID T. DAY is at the Palace hotel, San Francisco.
J. C. BRANNER has returned to Stanford from Brazil.
L. K. FLETCHER, of El Chico, Mexico, is in San Francisco.
F. LYNNWOOD GARRISON is on a vacation in Massachusetts.
ARTHUR FEUST is returning to New York from Nicaragua.
D. W. BAUNTON is spending a holiday at South Poland, Maine.

L. S. AUSTIN has returned to New York from British Guiana.

W. H. STORMS is in Calaveras county, engaged in professional work.

CHARLES A. CHASE has been at Ouray, Colorado, on examination work.

F. J. DENNIS is in North Carolina, engaged in mine examination work.

REX R. SEEBER is now manager for the Winona Copper Co., succeeding L. L. HUBBARD.

ROBERT H. RICHARDS has been spending a few days at Ishpeming on professional business.

A. L. DEAN has resigned from the Mount Lyell M. & R. Co., Ltd., at Queenstown, Tasmania.

F. M. SIMONDS is in Cuba on professional business. He expects to return to New York in November.

T. B. GREENFIELD has left Mexico and gone to the Ibutil mine, at Morriston, Madras Presidency, India.

DESAIX B. MYERS is in British Columbia for two or three weeks, and will return to Los Angeles on August 25.

R. A. F. PENROSE, Jr., and E. A. D'INVILLIERS are attending the International Geological Congress at Toronto.

L. D. RICKETTS is at Clifton, Arizona, to superintend the blowing in of the new smelter for the Arizona Copper Company.

H. RIES is in British Columbia, finishing an examination of the clays of western Canada for the Canadian Geological Survey.

FREDERICK G. CLAPP and ALLEN S. MILLER are examining the gasfields of Hungary in company with HUGO BOCKH of that country.

MARTIN J. HELLER is at Silverton looking after his interest in the Buffalo Boy property of the Continental Mining Company.

ROBERT SCOTT is at Lone, Nevada, installing one of his improved quicksilver furnaces, a 50-ton plant, for the Nevada Clinnabar Company.

F. L. SIZER, general superintendent of the Mascot Copper Co., Dos Cabezas, Arizona, has been examining mines in the Santa Catalina mountains, north of Tucson.

J. MALCOLM MACLAREN has recently been examining the Great Fingall and Fenian mines, and will later inspect the Sons of Gwalla and the Kalgoorlie group, in Western Australia.

C. R. WILFLEY, manager of the Barstow mine, Ouray, Colorado, is now residing at Denver, where he will continue as manager of the mine, and also take up private interests as well as consulting work.

LUDWIG H. DIEHL was in San Francisco on August 9. He has been to Western Australia in connection with the bromo-cyanide patent suit, and is now returning to London, stopping over at Cripple Creek, Colorado, on his journey across the United States.

The following members of the staff of the California State Mining Bureau are now doing field work: WALTER W. BRADLEY is examining conditions in Colusa, Glenn, Lake, Marin, Napa, Solano, Sonoma, and Yolo counties; S. L. LOWELL in Del Norte, Mendocino, Humboldt, and the west side of Trinity counties; ERROL MACBOYLE in Plumas, Sierra, Nevada, Placer, and Eldorado counties; R. T. McLOUGHLIN in Mono, Inyo, and Madera counties; and J. CHESTER BROWN in Siskiyou, Trinity, and Shasta counties. They will be out from 6 to 20 weeks.

The Metal Markets

LOCAL METAL PRICES

San Francisco, August 14.

Antimony.....	12-12½c	Quicksilver (flask).....	\$41
Electrolytic Copper.....	16-16½c	Tin.....	46-47½c
Pig Lead.....	4.75-5.70c	Spelter.....	7-7½c
Zinc dust, 1400 lb. casks, per 100 lb., small lots \$9.50-9.75; large \$7.50-8.50			

EASTERN METAL MARKETS.

(By wire from New York.)

NEW YORK, August 14.—Copper market is strong with electrolytic at nominally 15½c. Early deliveries are becoming scarce and spot delivery copper is unobtainable from the largest sellers for less than 16c. Cable from London reports all producers quoting 15½c. for October delivery. Spot is quoted at £69 17s. 6d. and futures £69 17s. 6d. A large decrease in August stocks is predicted, probably amounting to 20,000,000 lb. Lead is quiet with little trading reported. Spelter remains firm.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

June	61.29	59.03	Dec.	63.38

Writing on July 24, Samuel Montagu & Co. state that the upward tendency of silver prices has arisen from considerable buying, orders coming on a dull and inactive market. A certain amount of nervousness as to the effect of politics in China is undoubtedly responsible for these purchases, which introduce an element of uncertainty into a market scantily supplied from normal sources. The stock at Bombay has increased from £320,000 to £670,000, and the offtake is about 80 bars per day. Shanghai reports a stock of £5,825,000 compared with £5,750,000 last week. A shipment of £130,000 has been made from San Francisco to Hongkong. The quotations today for cash and two months delivery are 3s. 16d. above those fixed a week ago.

QUICKSILVER

The primary market for quicksilver is San Francisco, California, being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

COPPER PRODUCERS' ASSOCIATION REPORT

The Copper Producers' Association statement, August 8, shows a decreased surplus. The details are as follows:

	Pounds.
Stock of marketable copper of all kinds on hand at all points in the United States, July 1, 1913	52,904,606
Production of marketable copper in the United States from all domestic and foreign sources during July	138,074,606
Deliveries for consumption, July	58,904,191
Deliveries for export, July	78,480,071
Stock of marketable copper of all kinds on hand and at all points in the U. S., August 1....	53,594,941
Recent changes in surplus have been as follows, in pounds

*Full year.

THE COPPER SITUATION

With the Lake copper off the market entirely, it is therefore natural that copper continues to rise in price, the advance being helped by the fact that there is practically no metal available for spot delivery, the United Metals Selling Co. being reported to be the only agency which has any copper for delivery this month; indeed, the other large agencies are reported to be sold out for September delivery as well. London cables on August 7 stated that the Amalgamated and A. S. & R. agents were quoting £71 10s. for September and £71 15s. for October delivery. Large sellers in New York stated that an early advance to 16c. was imminent. On the other hand, an item in the Nevada Consolidated report for the second quarter of this year, showing 22,400,000 lb. on hand and in transit, sold and unsold, has been made the basis of much comment. The item is not especially remarkable, since it is well known that it requires about three months from the time of mining the ore to deliver refined copper, but it illustrated the amount of copper in the invisible stocks on each side of the refinery. The Lake mines are entirely out of production and the Butte mines are working on a reduced scale, but some of the Arizona properties are booming; Chino having made its high record to date last month.

The quarterly report of the Giroux Consolidated Copper Co., filed with the White Pine county, Nevada, assessor, is as follows:

Ore mined, tons	98,810
Gross value	\$380,976
Mining cost	169,195
Transport	24,419
Treatment	156,311
Net yield	31,051

Company Reports

ASSOCIATED GOLD MINES OF WESTERN AUSTRALIA, LTD.

This Company has 52 acres at Kalgoorlie, and a mill with a capacity of about 11,000 tons per month testing sulphide ore. The report covers operations during the year ended March 31, 1913. The articles of association of the Company have been altered to allow of its acquiring property outside of Western Australia, and with the Huronian Belt Syndicate, Ltd., has secured an option on the Keeley mine, at South Lorrain, near Cobalt, Ontario.

The report of Duncan F. McAulay, the general manager, contains the following notes on the year's operations at Kalgoorlie. Mine development covered 6776 ft., of which 2457 was in unprofitable ore in six different lodes, and 879 ft. in ore worth \$4.80 and over per ton. The width of profitable ore sampled was 60 in., averaging \$10.32 per ton. The usual development was done on the Australian East, West, North, Cross, Central Boulder, and No. 7 Shaft lodes, the first named producing nearly 50% of the ore mined. Owing to the nature of the ore-shoots, an estimate of ore reserves is most difficult, but it might be said that development has nearly kept up with ore extraction. Broken ore in stopes amounts to 43,199 tons worth \$5.60 per ton, which is indicative that the maintenance of a mill value equal to that of last year is doubtful. However, there are several encouraging points, namely, the north branch of the West lode, the Australia East lode, over No. 17 level, and the new work on the latter lode between No. 2 and No. 5 levels, which, apart from an unforeseen but possible improvement in some of the existing stopes, may enable the present mill average to be approximately maintained. But a daily working connection with the mine for a further year has, if possible, brought greater conviction than before of the futility of any forecast. Results were as follows:

Ore treated, tons.....	125,169
Gold output, ounces.....	37,892
Silver, ounces	826
Total value	\$773,000
Mining, treatment, general, and plant expense....	672,000
Balance	\$101,000
Dividend	58,000
Value of investments	600,000
Depreciation (development and machinery).....	105,000
Production to date:	
Ore treated, tons	1,387,097
Value	\$16,150,000
Dividends	3,500,000

SIMMER DEEP, LTD.

This Company was registered in 1906 to acquire property lying to the south of the Simmer & Jack mine on the Witwatersrand goldfield, Transvaal. The capital consists of 1,750,000 shares of \$4.80 each, of which 1,650,000 shares have been issued fully paid, leaving 100,000 shares held in reserve. The mine is low grade, profit being dependent on low working costs, which can be achieved only by dealing with a large tonnage and with cheap unskilled labor. As compared with 1911 the report for 1912 shows 52,950 more tons treated, the average recovery being \$4.22 as against \$4.50, the working cost per ton \$3.92 as against \$3.93, the net result being a working profit of \$172,000, or \$100,000 less than for 1911. Attention has been given to securing better health conditions underground, and as there is a decided tendency toward an improved native labor supply, it is hoped the mine will soon be working on a larger scale. The estimated ore reserve December 31, 1912, was 1,430,393 tons, fully developed, of an average value of \$4.20 per ton, and 144,292 tons, partly developed, of an average value of \$4.08 per ton. The fully developed ore reserves the year before were estimated to be 1,469,719 tons of an average value of \$4.40. The profits from operations for the year were \$249,000 as against a debit

account of \$268,000, leaving a net loss for the year of \$19,500.

SHAMVA MINES, LTD.

This Company was formed in 1910, with a capital of £600,000, and took over 243 mining claims in the Abercorn district of Rhodesia from the Abercorn Syndicate and the Mayo Development Co., Ltd., for £250,000 in fully paid shares. Other claims have since been bought, bringing the total up to 523 claims. The mine has been in course of development and a mill consisting of 56 Njssen stamps and 10 tube-mills is in course of erection. It was expected that this would begin operation in the course of the summer, but construction work has been delayed through lack of railway facilities, as the extension of the Blinkwater railway was not completed until April 24, instead of December last, as expected, and it is probable that the

MAP OF RHODESIA.

mill will not be started before the end of 1913 or early in 1914. Development work during the past year amounted to 3610 ft. On March 31, 1913, the estimated ore reserves were 2,319,752 tons, of an average assay value of \$5, as against 2,091,859 tons on March 31, 1912, of an average assay value of \$4.97. By March 31 of this year 165,172 tons was broken and ready for the mill. The following figures give the development costs, both for machines and by hand, also for the main adit:

	Feet.	Per foot.
Machines	1472	£5 3s. 8d.
Hand	1417	£2 6s. 9d.
Main adit	721	£2 6s. 7d.

These costs do not include Bulawayo and general expenses, which amounted to a total of £5992, and depreciation account, amounting to £4863. The stoping costs on 123,692 tons broken during the year amounted to an average of 12 pence per ton. Satisfactory progress has been made in the mine, and although the width and length of the orebodies on the No. 3 level do not compare with those on the No. 2 level, yet the tonnage produced shows a higher average value; namely, \$6.42, against \$5.78.

ANTELOPE GOLD MINE (RHODESIA), LTD.

This Company was registered in 1908 and owns 170 mining claims in the West Gwanda district of Rhodesia, also the farm, Tabas N'Yoni, on which the claims are located. Good progress has been made with the reduction

plant, and it is hoped that it will be ready to start work about September next. The ore reserves on December 31, 1912, were 124,601 tons of \$10.10, and 6217 tons of \$8.30, and 14,579 tons of \$5.90. The total development done to December 31, 1912, amounted to 23,401 ft. The increase in tonnage developed during the year amounted to 22,000 tons. Native labor has been found ample. A shortage in rain has retarded forwarding the machinery, as no grass could grow in the district and all animals engaged on the 50-mile haul from the railroad to the mine had to be provided with fodder from the railway. The water problem has now been solved by the erection of a dam.

THE ANGLO-FRENCH EXPLORATION COMPANY

The Company was registered in 1907 as the Anglo-French Exploration Company of the French Congo. The authorized capital is 150,000 shares of \$4.80 each. The Company holds shares in a number of mining ventures, but does not itself operate mines. There is an engineering department in Johannesburg, which showed a debit balance for the year in the report for 1912, as owing to the depressed times and to the suspension of operations by certain companies, the amount earned in fees shows a diminution. The Van Ryn Deep, in which the Company has a large interest, is developing satisfactorily and was expected to commence crushing in July 1913. The labor position is improved, coöperation being secured between the mines by a new organization, the Native Recruiting Corporation. The total assets of the Company for the year are \$5,136,000 as compared with \$4,820,000 the year before. A dividend of 6% was paid on the ordinary shares.

THE CASH MINE COMPANY

This Company is capitalized at \$1,000,000 in shares of \$5 each, of which 57,403 have been issued, and has \$37,500 in outstanding bonds and notes. The Company's property is at Magnolia, Boulder county, Colorado, and consists of two patented mining claims. The main working shaft is down 465 ft., midway along the strike of the vein, which is approximately 2400 ft. long; drifts have been extended on five different levels. The ore is estimated to average \$15 per ton; mining and milling expenses are about \$6 per ton. The mine plant is equipped with electric machinery and mine equipment for handling from 30 to 40 tons of ore per day. The mill is designed for roasting and cyanide leaching, and is limited to the capacity of the roasting furnace, which is from 20 to 25 tons per day. With more cyanide solution storage capacity and several minor additions of small cost, the mill, by doubling the roasting equipment, can treat 40 to 50 tons per day. Sufficient working capital is now being arranged for, and it is hoped that the property will be put in operation in the near future. Assets include \$61,000 of equipment and 6000 tons of ore with a net value of \$50,000, while in the liabilities are bonds, notes, and other liabilities of \$42,831.

PODEROSA MINING COMPANY, LTD.

This Company was registered in 1908, to acquire 37 mining claims in the Collahuasi district, province of Tarapaca, Chile, South America. The mine has an unfortunate situation, the ground being heavy and the water troublesome in the deeper part of the mine, making it necessary to timber in advance. It is difficult on account of these and other reasons to obtain workmen. In 1909 a dividend of 5% was paid, and that added to the loss already incurred made a deficit of \$321,000 to be carried forward. No dividends have since been paid, but the report for 1912 shows the debit balance to be changed to a credit balance of \$34,000, which the directors propose to carry forward. During 1912 the total hoisted from the mines amounted to 32,515 tons, about one-third of it ore, the rest waste. Most of this came from the Poderosa and Rosario mines, but the Venus mine is promising very well. The amount of ore shipped to Mejillones during 1912 was 11,318 tons, with an assay of 22.02% copper and 8.8 oz. of silver per ton. The product in pure copper, according to these figures, should be about 2492 tons, and deducting 1.3% for moisture from the assay value, the result would

be approximately 2267 tons as the production of the year. The mine manager, C. Crempien, estimates the ore reserves on December 31, 1912, at 15,760 tons of 21% copper ore.

THE BUFFALO MINES, LTD.

The seventh annual report of this Company, covering the period from May 1, 1912, to April 30, 1913, shows that the mill treated during the year 55,783 tons of ore, averaging 45.83 oz. of silver per ton, or a total of 2,556,403 oz., of which 82.64%, or a total of 2,112,684, was recovered as follows: 39,798 oz. in metallics, 982,697 oz. in jig concentrate, and 1,090,189 oz. in table concentrate. The cyanide plant treated during the year 10,320 tons of slime concentrate from the mill, averaging 15.45 oz. per ton, or 159,511 oz. treated, of which 74.70%, or 119,160 oz., was recovered in precipitate. The new amalgamation plant and refinery began operation the latter part of November 1912, and to April 30, 1913, the plant treated 222 tons of table concentrate and 182 tons of jig concentrate from the low-grade mill, and 35 tons of high-grade ore direct from the mine. There was also refined at the plant 1438 lb. of metallics from the low-grade mill, 8012 lb. of precipitate from the cyanide plant, and 821 lb. of base bullion. The total production of refined bullion from this plant was 764,030 oz. of fine silver. During the year 28 cars of ore were shipped, containing 726 tons of concentrate from the low-grade mill and 35½ tons of high-grade ore direct from the mine, or a total of 761½ tons shipped, and some small sales of native silver, the returns of which amounted to 1,147,966 oz. There was also shipped during the year 56,431 lb. of bullion, the returns for which amounted to 818,246 oz. There was on hand at April 30 a total of 269,641 oz. Returns from ore and bullion shipped, sales of native silver and ore, etc. on hand, make a total production for the year of 2,235,853 oz. The ore reserves developed were approximately 57,330 tons of about 30-oz. ore, or 1,719,900 oz. This is about equal to the tonnage mined during the year, but slightly less in ounces. The development has been mainly along branch veins on third level No. 5, with the additional ore developed in the Nancy-Helen workings, also on the first level No. 7. Comparing the production, recovery, and profit with the previous year, the mill handled 8982 tons more. The average value of ore per ton treated in the mill was 13.48 oz. higher. The total recovery was 710,591 oz. greater. Net receipts were larger by \$440,038.80. The cyanide plant recovery was two and a half times greater. Total earnings were \$1,258,864.34; operating expenses \$310,279.80; and administration \$57,391.58; a net income of \$891,193. Dividends paid during the year amounted to \$656,000. The total surplus, April 30, 1913, was \$623,028.

ZEEHAN-MONTANA MINE, LTD.

The Company was registered in 1892 to acquire silver and lead mining property in the Mount Zeehan silver field of Tasmania. Since then, the adjoining property of the Tasmania Crown Silver Mining Co., Ltd., has been purchased, also 200 acres was taken under the Mineral Lands Act, and a portion of the adjoining Silver Queen property was purchased, making a total of 420 acres. The mine has been in constant operation for twenty years, and dividends have been paid except from December 2, 1908, to January 8, 1911. The general manager, J. Craze, found more reserves of ore, and since then dividends have been resumed. The net profit for 1912 amounted to \$5700. A dividend of 12c. per share was distributed in May 1912, and a balance of \$9600, the profits for 1912 plus the balance of profit in hand, was recommended to be carried forward. The ore shipped to Antwerp was 1200 tons, with a net value of \$96,000. According to the contract with the Tasmania Smelting Co., all surplus ore and concentrate over 100 tons per month was sold to that Company, a net product of \$19,000. Although the old levels are almost exhausted, there is yet a good deal of virgin ground to be explored, and it is probable that profitable reserves may be found. The concentrating plants treated 9980 tons of second-class ore during the year, at a cost of 87c. per ton.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

SHAFT-SINKING through gravel and sand at Poseidon, Victoria, Australia, is being done by the freezing process.

EIGHT Holman pneumatic stamps at the East Pool & Agar tin mine, Cornwall, working 26 days, crushed 5637 tons of dry ore in June.

COKED DUST, blistered coal, and stalactitic carbon were found in the Bureau of Mines experimental mine, at Pittsburgh, after explosions had taken place.

ROADS AND TRAILS constructed in Alaska to June 30, 1911, totaled 2891 miles, costing \$1,869,890, an average of \$645 per mile, including maintenance and repairs.

OVERBURDEN and tin drift amounting to 37,000 cu. yd. was removed in June from the Briseis tin properties, Tasmania, resulting in a clean-up of 45 tons of black tin.

ROCK-DRILLING CONTESTS at Fairbanks, Alaska, on July 4 resulted in the \$250 prize being won by Colin F. McGilivray and David Browner, who drilled 33¼ inches in 15 minutes.

SHAFT-SINKING and other costs at the Buckeye Belmont mine, Tonopah, during the first half of the current year, were as follows: Sinking, \$34.03 to \$36.30; cutting station, \$17.43; and cross-cutting, \$10.61 to \$16.12 per foot.

AUTOMOBILES are now being used successfully in Alaska and the Yukon, in handling freight and passengers. From Fairbanks to Valdez, 363 miles, was recently covered in 54 hours, and Dawson to White Horse, 365 miles, in 33 hours.

THE Corozal established a new record for one day for ladder dredges in the Canal service, on Friday, July 11, by excavating 13,700 cu. yd. of material, 90% of which was rock, in 19 hr. 50 min. actual working time, an average of about 685 cu. yd. per hour.

WATER from the Barnes mine, Quartz hill, Gilpin county, Colorado, has hindered amalgamation at the U. P. R. mill. The water is strongly acid and contains copper, and pipes and other metals are rapidly corroded. It is proposed to let the water flow over the scrap iron in launders between the mill and mine.

ANDESITE containing thin flakes of native silver has been found on the picking belt at the Tonopah-Belmont mine, Nevada. This is an unusual occurrence, and it has not been found in place in the mine so far. The rock is probably a somewhat altered trachyte that would contain about 66% silica.

THE PRINCESS PIT, now known as Sydney No. 1, of the Nova Scotia Steel & Coal Co., was in 1873 the first submarine mine in North America, the coal being won from workings under the sea. The shafts are of unique construction, consisting of metal cribbing or tubbing. The total length of metal tubing is 842¾ ft., weighing 776 tons.

SINCE 58% of all industrial accidents are shown by statistics to be due to negligence, carelessness, or lack of knowledge of employers and employees, the vital necessity of learning everything possible about the causes and means of preventing these accidents must be evident to every man concerned in mining. To the operators it spells business success or failure; to the miner, life or the physical ability to work and support a family.

ACCORDING to the electrolytic theory of corrosion, when iron is oxidized in the wet way it first goes into solution as ferrous ions. The ferrous ions are then oxidized by the oxygen present in the water to ferric ions and are precipitated as ferric hydroxide. Simultaneously with

the formation of ferrous ions, hydrogen is liberated on the surface of the iron. The passage of the iron from the atomic to the ionic state and the passage of the hydrogen from the ionic to the atomic state are accompanied by a transfer of electricity. The ferrous ions derive from the metal surface a charge of positive electricity, the hydrogen ions give up a charge of positive electricity, and a current flows through the metal from the point where hydrogen is liberated to the point where iron is dissolved.

CISTERNS that are properly constructed and receive rain water from roofs generally afford water of good sanitary quality, but if water of doubtful quality is stored in cisterns the supply is, of course, not safe for domestic use. Filters used in connection with cisterns are of value in making the water clear, but are generally of no value in removing disease germs. Many cisterns are divided into two parts by a brick wall, the water being admitted into one compartment and drawn from the other. In such cisterns the water passes through the brick, and in that way is improved in clearness and color, but not generally in sanitary quality.

THE PULP RESIDUE from manufacture of sugar beet is valuable, among other things, as fodder for stock and as a fertilizer. The manure from animals fed on molasses contains valuable potash and nitrogen of the latter, and the use of such as a fertilizer has all the advantages and none of the disadvantages which result from the direct application of molasses to the soil. The approximate average composition of beet molasses in Germany, according to C. A. Browne, from which no more sucrose will crystallize is as follows: water, 20%; sucrose, 50%; salts, 10% (5% K₂O); nitrogenous substances, 10% (2% N); and gums, acids, etc., 10%. These figures suggest at once that molasses might have some value as a fertilizer; and such in fact has been demonstrated to be the case upon certain kinds of soil, more especially those deficient in humus. The application of molasses to other soils, however, has caused an acid fermentation with souring of the soil and loss of fertility, so that this method of utilizing molasses is not always successful. The press-cake obtained from cane sugar consists of fine particles of bagasse ground off in milling, with an admixture of wax, proteins, gums, lime sulphate and phosphate, iron oxide and alumina, and considerable earthy matter which was brought in on the cane stalks from the field. Where the carbonation process of clarification is used, as is the case with beet-sugar manufacture, the press-cake is mostly calcium carbonate, the remainder consisting of the wax, proteins, gums, etc., found in defecation press-cake. Great benefit has been derived from the use of filter-press cake as a fertilizer, the nitrogen existing in a form which is readily available. The excess of calcium carbonate in carbonation cake has also been found beneficial upon certain soils. The employment of press-cake as fertilizer is about the only means of utilization. In the manufacture of beet sugar, lime is used to clarify the juice before concentration. By use of the lime the organic matter other than the sugar coming from the beets is precipitated. This organic matter is composed chiefly of nitrogenous material, but also contains various minerals including potassium and phosphorus. Any excess of burned lime is precipitated by running carbon-dioxide gas through the juice. The whole material is then passed through the filter-press, which separates the burned lime in the form of calcium carbonate or limestone together with the organic matter of the juice, which includes potassium, phosphorus, and nitrogen. Lime acts on the soil both physically and chemically, according to Charles S. Knight of Fallon, Nevada. Its chief physical effect is upon heavy soils, making them more receptive to water and permitting better drainage. Probably the most important chemical effect of lime is the neutralization of organic acids as they are formed in the soil by the decomposition of vegetable matter. Besides, lime forms an important food material for the lower organisms in the soil, and also helps to a considerable extent in rendering the potassium, phosphoric acid, and nitrogen in the soil available as food for the growing plants.

Book Reviews

STEAM POWER PLANT ENGINEERING. By G. F. Gebhardt. Fourth edition, entirely revised. P. 989. Ill., index. John Wiley & Sons, New York. For sale by the *Mining and Scientific Press*. Price \$4 postpaid.

Engineers will welcome the revised edition of this old friend, and will be glad to note that the author and publishers have coöperated to reduce the cost of living by making the price \$4 instead of the previously rather high figure of \$6. To quote from the preface the changes are as follows:

"The chapters on Fuels and Combustion, Engines, Turbines, Condensers, Finance, and Economics, have been entirely rewritten and others have been revised and enlarged. The chapter on Finance and Economics contains many operating charts, showing current practice in power plant cost and accounting, typical load curves illustrating daily, monthly, and yearly load characteristics for a wide range in practice, and numerous tables giving recent results in cost of operation. Over three hundred new illustrations have been added, and the entire text has been reset."

GENERAL AND INDUSTRIAL ORGANIC CHEMISTRY. By Ettore Molinari. Translated by Thomas H. Pope. 770 pp.; 506 ill. P. Blakiston's Son & Co., Philadelphia, 1913. For sale by the *Mining and Scientific Press*. Price \$6.

As a sequel of Mr. Molinari's monumental work, 'General and Industrial Inorganic Chemistry,' the present volume is a most valuable addition, dealing as it does with that interesting branch of the science which has shown such a marked development of late years. It is only necessary to recall the advance which has taken place in the manufacture of artificial gas with its innumerable by-products, and refining of petroleum as well, to realize the extent of application of organic chemistry and its importance in the industries. Sugar refining, starch manufacture, the making of alcohol, wines, yeast, beer, and ferments has been an especially productive field for organic research. In the textile industries, organic chemistry has found a valuable application in the testing of fibres, analysis of mixtures of textile fibres, dyeing, and printing. In the present work there is presented that happy combination of the theoretical and practical which is lacking in most works of this nature, the practical side of the subject being so hidden that to one who is not an absolute theorist the work is exceedingly tedious. The practical or commercial side of the subject is written in a manner full of human interest, which with the abundance of illustrations present the text in a way which appeals to the eye as well as the intellect. With modern environment it does not suffice that the young chemist should have a thorough knowledge, for instance, of the various syntheses and constitutional formulae for sugars. He should at least be acquainted with the general outlines of the industrial processes and of the technique of the manufacture of sugar, beginning with the slicing of the beets and proceeding to the exhaustion of the pulp, defecation, saturation, filtration, boiling, vacuum concentration in multiple-effect apparatus, refining, utilization of the residue, and so on. He should understand the plant and chemical processes of the more important industries, as these often find application in the manufacture of products of a secondary or entirely new character. What would avail a study of the wonderful artificial coloring-matters derived from coal-tar if it were limited to a simple mnemonic exercise for the student and no notice were taken of the interesting practical application to the dyeing of the various textile fibres? It has been the object of this work to present a suitable fusion of these two sides of the subject.

Among the subjects discussed are included illuminating gas, furnaces and retorts, purifiers, gas testing, petroleum, distillation, purification, desulphurizing, methods of testing, treatment of residues, asphalt, acetylene, fermentation, yeast, alcoholometry, brewing, ethers, explosives, organic acids, soap, sugar, starch, dyes, etc. The scope of

the work is exceedingly broad, and while it cannot be said that all the minute details have been covered, as a general survey of the subject the work presents a most valuable addition to the literature of this science.

Recent Publications

BIBLIOGRAPHY OF SMOKE AND SMOKE PREVENTION. Compiled by Ellwood H. McClelland. Smoke Investigation Bulletin No. 2. P. 164. University of Pittsburgh, Pennsylvania, 1913. This is an interesting bibliography of the subject dealing mainly with coal smoke, and does not include the literature of dust, metallurgical fumes, firing, and other subjects more or less related to the suppression of smoke.

AMERICAN MINING CONGRESS. Report of the proceedings of the fifteenth annual session held at Spokane, Washington, November 25 to 29, 1912. P. 251. Denver, Colorado, 1913. This volume includes the annual address of the president, and the following papers: 'National Forests and Development of Natural Resources'; 'Protection of Investors in Mining Stocks'; 'The Relative Hazard of All Vocations in Comparison with Mining'; 'Government Construction of Railroads and Leasing of Coal Lands'; 'A "Day in Court" for the Alaska Coal Claimants'; 'Law Enforcement for Alaska'; 'Transportation Facilities in Alaska'; 'The Leasing of Mineral Lands'; 'Mineral Land Laws and the Decadence of Prospecting'; 'The Washington Compensation Act'; and three papers on 'Workmen's Compensation.'

THE NICKEL INDUSTRY. With special reference to the Sudbury region, Ontario. By A. P. Coleman. Department of Mines Monograph. P. 206. Ill., maps, index. Ottawa, 1913. This is a valuable contribution to the growing nickel industry. The use of nickel in steel adds greatly to its strength, reducing the quantity of steel needed in structures and the cost. The Sudbury district is the most important nickel ore producer in the world, the annual output being about 700,000 tons, the next in importance being the French island of New Caledonia, 900 miles east of Australia, which produces about 120,000 tons of ore. In the volume under review the following points are dealt with: general geology of the Sudbury district, historical sketch of development, the various companies operating, description of the nickel ores, source of the ores, individual deposits and methods of working, other Canadian nickel deposits, with those in the United States, Cuba, Europe, New Caledonia, and Cape Colony, mechanical treatment of Sudbury ores, metallurgical processes, uses of nickel, what is monel metal, and an appendix dealing with patents for separation of nickel and copper, and refining of nickel. The book is well illustrated.

Bureau of Mines publications, Washington, 1913:

AN ELECTROLYTIC METHOD OF PREVENTING CORROSION OF IRON AND STEEL. By J. K. Clement and L. V. Walker. Technical Paper No. 15. P. 19.

FIRST SERIES OF COAL-DUST EXPLOSION TESTS IN THE EXPERIMENTAL MINE. By George S. Rice, L. M. Jones, J. K. Clement, and W. L. Egly. Bulletin 56. P. 115. Ill. The Bureau of Mines has spent a considerable amount of time and money in making these tests, since the idea was adopted in 1910. For the purpose a new mine was developed to the extent desirable, and then the tests were begun to determine the natural laws underlying ignitions and explosions in coal mines. Lessons from these tests showed the following among others: that an explosion could be obtained by a single blown-out shot at the face; coal-dust explosions may occur when the atmosphere is nearly saturated, and the floor, ribs, and walls are damp, but not wet, provided the coal-dust is dry and sufficiently abundant; and the comparatively slow development of some explosions, the relatively slow speed of the pressure wave, and the rapid overtaking of the pressure wave by the flame of the explosions.

Improved Automatic Water Gauge

The improved automatic water gauge herewith illustrated, was designed and patented by the Lunkenheimer Co., of Cincinnati, Ohio. The gauges are made in two patterns, termed 'medium' and 'extra heavy,' and are intended for 200 and 300 lb. working pressures. Should the gauge glass break, the ball check-valves *K* will automatically seat themselves, owing to the rush of steam and water on the side thereof, and the lack of pressure on the other. This automatic closing feature is a valuable one, as it prevents the escape of steam and water, and permits the safe closing of the hand-operated valves for the purpose of renewing the glass. To renew the glass, it is only necessary to loosen the stuffing-boxes *G*, take off the cap *C*, remove the broken glass and substitute a new one, after which the stuffing-boxes are tightened and the cap *C* replaced. The change can be performed with perfect safety, for owing to the quick-closing valves, which should be closed upon the discovery of the broken glass, there is no danger to be anticipated from escaping steam and water.

Care has been exercised in the design to facilitate cleaning, and access can be readily had to any part. The plugs *C*, *D*, *R*, and *N* are provided for this purpose. By removing the plugs *D* and opening the re-grinding valves to their greatest extent, a rod can be inserted entirely through the body and tail-pieces, and any sediment that might have collected in or around the entrance of the tail-pieces can thereby be easily removed. By unscrewing plugs *E* and *N*, the check-balls will of their own accord fall from the body, as they rest on inclined surfaces. The arrangement illustrated herewith was designed, as will readily be seen, so that both valves can be made to positively seat independently of each other. This arrangement consists of a block pulley operating over a chain, which is pinned to both the upper and lower pulleys, this method being employed for closing the valves. Should one of the valves become closed before the other, a continued pull on the block-chain will close the other. The valve-seat opening is large, and consequently a free and unobstructed passage for the water and steam is insured. The gauge cannot show a false level, as the ball-checks are so constructed that unless the glass breaks, they will, owing to their weight and position, fall away from their seats. The Lunkenheimer Co. has issued an attractive booklet describing this gauge, which is being distributed free to anyone desiring a copy. The gauge has been given the trade name of 'Monitor.'

Drilling Equipment at Mt. Royal

The air for operating the entire outfit of Sullivan drills, now in use in the Mt. Royal tunnel, and the hammer drills used for putting in holes for supports for ventilating pipe and light wires, is furnished by two direct-connected compressors of Sullivan 'WN-2' type, 2000 ft. capacity at 100 lb. pressure. One is situated at each end of the work, and in addition to the direct-connected compressors, there are also Blaisdell belt-driven units of about 1100 ft. capacity at each end of the work, making a total of 5300 ft. at each end of the tunnel. The Sullivan 'WN-2' compressor is so well known for its reliability to work and efficiency that it needs no further description.

According to the figures considered that in driving this 810 ft. of 8 by 8 iron is oxidized in the crew at Mt. Royal drilled a total of 20% as ferrous ions. The excavated a total of 18% more hard rock the oxygen present in the Loetschberg tunnel in driving precipitated as soft rock, a world's record can hardly be dis-

puted for tunnel driving where air-driven percussive drills were used.

Four 'FF-12' Sullivan reciprocating percussive drills of water type, using hollow steel 1½ in. diam., through which alternate pulsations of air and water are forced to the bottom of the hole, were used in this heading. 'FJAB' steel was used, made up in 22-in. changes; about 500 sharp steels were used each 24 hours. When the hard dikes were numerous, it greatly exceeded this number. The gauges were as follows:

	Cuts to in.	Gauge, in.
Starter	22	2¼
No. 2	44	1¾
No. 3	66	1¾
No. 4	88	1½
No. 5	110	1¾

The No. 5 was rarely used, and the gauge of 2¼ in. on the starter was used to give more freedom at the collar of the hole, also making it easier to remove the steel. The size of hole required at the bottom was only large enough to receive 1¼-in. dynamite.—*Mine and Quarry.*

Commercial Paragraphs

The HARDINGE CONICAL MILL Co. reports that, after operating two Hardinge mills for fourteen months, the Tom-boy Gold Mines Co. is installing two additional mills of the same type.

The new Equitable Life Insurance building in New York, 38 stories high, will contain approximately 36,000 tons of structural steel, the inspection of which, both mill and shop, has been intrusted to ROBERT W. HUNT & COMPANY.

In accordance with its long established policy of business expansion, H. W. JOHNS-MANVILLE Co. has recently opened a branch office at Charlotte, North Carolina. The new office, which is in the Commercial Bank building, is in charge of E. U. Heslop, who is assisted in covering the western part of North Carolina by P. J. McCusker and Paul W. Whitlock.

The DODGE MANUFACTURING Co., of Pittsburgh, has contracted with the FAIRMONT MINING MACHINERY Co. of Fairmont, West Virginia, for a carload of self-oiling ball-and-socket pillow blocks (dustproof), adjustable floor stands of special designs, and standard split iron pulleys, the latter to weigh about 2400 lb. finished. The adjustable floor-stands, according to specifications, will each be 58½ in. high to shaft centre.

The NATIONAL TUBE Co. announces that it has entered the electrical conduit field and that it has contracted with the National Metal Molding Co. and the Safety-Armorite Conduit Co., both of Pittsburgh, Pennsylvania, to manufacture and sell this product for it as its agents, under the various brands. It has also been decided to sell this product on the 'Pittsburgh basing discount' plan in the same manner as all wrought pipe for other purposes has been sold for the past thirteen years.

The Inspiration Copper Co. has just purchased two double-drum hoists, to be built by the NORDBERG MFG. Co., of Milwaukee, Wis. Each hoist is designed to lift the following load: ore, 24,000 lb.; skip, 12,000 lb.; rope, 1¾ in. This load is to be lifted in balance from the present working depth of 650 ft., at a hoisting speed of 750 ft. per minute. Each hoist will have two drums, 10 ft. diam. by 65-in. face, grooved for 1000 ft. of 1¾-in. rope. One drum will be keyed to the shaft, the other equipped with the Nordberg axial clutch. Both drums will be equipped with Nordberg post brakes with parallel motion supports. Clutch and brakes will be actuated by Nordberg air-operated thrust cylinders with oil cataract cylinders and the Nordberg floating lever mechanism, for flexibility of control and positive locking of brakes for any position of the operating lever. The normal hoisting rate will be 30 trips per hour, or 5000 tons of ore in 14 hours for one hoist. The hoists will be driven through Wuest herringbone gears by General Electric direct-current motors operated by an Ilgner motor generator set.

EDITORIAL

MOTHER JONES has left the Superior district for Washington. With the present attitude of the Administration toward lobbyists, it is a question whether a hearty welcome into the inner circle of the Solons will be accorded, or the greeting which awaited 'General' Coxe, to 'keep off the grass', will be the order of the day.

THE closing of the famous old Lundberg, Dorr & Wilson property, as recorded in the current issue, marks the passing of one of the old pioneer properties which, during a long life of usefulness, has added a full quota to the advancement of the science of metallurgy. The results of the experimental work as conducted at this mill and the refinements of the cyanide process as developed in the treatment of the ores of this property, have been far reaching in effect and can be seen in almost every mining district of importance in which cyanidation is practised.

WIRELESS TELEGRAPHY is finding an important use in connection with mining operations in Mexico. Owing to the constant interruption of the ordinary service, because of the activity of the 'revolutionists', a wireless service has been installed at some of the more important properties and direct telegraphic communication is now being maintained between these properties and their anxious owners on this side of the Rio Grande. While an aerial fleet for the transport of bullion and supplies has not as yet made its appearance, it would seem that some such means of transportation will have to be devised if the mines and mills are to be kept in operation.

IN the present issue we publish the last of the series of articles by Mr. A. Sydney Additon on 'Under-Estimating the Cost of Milling Plants.' While no two general managers or boards of directors will agree as to the one most economical and efficient method of mill construction, and the general methods of contracting and professional supervision are subjects which can not be decided by a rule of thumb, but must be adjusted to fit the particular case under consideration, there are, however, fundamental principles which might well be called 'horse-sense' in mill construction, which are often neglected. The subject of design and supervision is, of course, one which offers a great field for difference of opinion as to policy and method. The position of the large machinery houses in acting as both metallurgical adviser and contractor

is often criticized and many times unjustly, as the field which is occupied by the machinery manufacturer, especially as adviser to the small operator, is an important one by which the operator has profited on innumerable occasions. Our attention is called to one particular example where the identical equipment for a 10-stamp mill, when erected and placed in operation under the supervision of a competent engineer, was 40 per cent in excess of a contract price offered for the same work by a machinery house. While this case can not be looked upon as the rule, such cases are numerous and would tend to show that the matter of design, supervision, and contracts is one in which the machinery house holds an important position, which in many cases may be taken advantage of by the prospective builder. In the construction of milling plants the preliminary work is of the greatest importance, as the success or failure of the completed plant is largely dependent upon the accuracy of this investigation, and it is to be noted that in our most successful mills the process and design have only been arrived at after the most careful investigation by the best metallurgical talent. The 'pilot' mill or test unit has been proved the logical forerunner of large plants, and the comparatively large amount of capital expended in equipment and preliminary ore testing under expert supervision is conceded to be money well invested. These are facts which are attested to by the number of derelict mills, and mills which have had to be practically rebuilt after being erected. A closer relationship between the machinery manufacturer and the metallurgical engineer would undoubtedly redound to their mutual benefit as well as advance the interest of the operator, as it is only by the avoidance of this friction, which occasionally makes an appearance, that the best results are to be obtained.

THE Butte meeting of the American Institute of Mining Engineers has been one of the most successful in the history of the organization. One hundred and forty members registered for the session, among whom were some of the most eminent engineers that the industry affords. The technical program is conceded as the best which has been rendered in years, the papers presented on concentration being of especial interest and value. The exceedingly liberal attitude of the Anaconda company in the matter of furnishing complete information and data regarding the operations at this property is to be commended and has proved of great interest to the visiting engineers. The sessions at Butte, Anaconda, Great Falls, and Southern Cross have all been well attended and keen interest has been taken in the papers presented. The social program has been most attractive, and while properly subordinate to the main purpose of the meeting, the departing engineers will carry away remembrances of a few days well spent in a most enjoyable holiday. The mine rescue car, which accompanied the engineers' excursion train, proved both interesting and instructive. The demonstration of the use of this comparatively new factor in mine rescue work is conclusive as to its value as an aid in the great humanitarian service, for which it was designed.

The Brown Process Decision

The recent decision of Judge Edward G. Bradford in the District Court of the United States for the District of Delaware, in the suit of Joseph A. Vincent *versus* Tonopah Mining Company of Nevada and Desert Power & Mill Company, is one of most importance in that it pertains directly to a branch of milling practice which has come to be recognized as standard for the treatment of ores containing the precious metals. The patent in suit was that granted to Alden H. Brown for 'Improvements in Processes for the Treatment of Precious Metal Bearing Ores,' on February 7, 1905. The scope of the decision, which was rendered in favor of the complainant and held that an infringement had been made by the Tonopah company, may be judged from the grounds for the suit, or the practice at the Tonopah mill, which has been adjudged an infringement. The patent claims a process for the treatment of precious metal bearing ores by cyanide solution followed by classification, leaching, and concentration. The process as patented is in contradistinction to the practice to treat first by concentration and secondly by cyanidation, it being held as a reversal of this process with the addition of certain special features in connection with cyanidation. The advantage in treating many ores by this system, it is claimed, is due to the fact that in the case of most gold and silver-bearing ores, the use of water in crushing by stamps or rolls or in connection with concentration occasions much loss of metal by 'sliming' because a large percentage of the metal content is reduced to so fine a state of division, that it is taken up in suspension by the water used, making it difficult to settle that portion of the metal content for further treatment within the limits of a plant of ordinary construction, as it remains in suspension for many hours. In the treatment patented the metal content of the fine material is recovered by the cyanide process in the beginning, leaving only the coarser material, which is readily recoverable by concentration. The special features claimed for the patent consist in decreasing the volume of solution used by settling, and pumping back the solution to the stamp-battery and the use of cyanide solution to create the ascending current in the classifier. The charge of infringement has been granted on one claim, which is as follows: The herein described process for the treatment of ore consisting in, first, pulverizing the ore in the presence of cyanide solution; second, subjecting the ore to hydraulic classification by the introduction of cyanide solution at the bottom of an overflow-tank to produce an ascending current; third, leaching the ore by the use of cyanide solution, whereby the finer metal content of the ore is dissolved; fourth, removing the dissolved metal from the ore in any suitable manner; and finally subjecting the residue to concentration.

In summing up, Judge Bradford holds that the defendants have used in their process all of the steps contained in the complainant's process and in the order required by the patent. That there is, first, the pulverizing of the ore in the presence of cyanide solution in the stamp-battery; second, the subjection of the ore to hydraulic classification with-

in the meaning of the second step; third, leaching of the ore, not only in the stamp-battery, but in the Huntington mills by the use of cyanide solution, whereby the finer content of the ore is dissolved; fourth, the removing of the dissolved metallic content of the ore to the concentrating tables; and finally, the subjection of the residue of the ore to concentration. While the defendants have added a number of steps or features not included or required in the patent, the court holds that these features do not operate to negative infringement of the combination process as embodied in the earlier steps of the process practised by them, and that the patent in suit must be sustained and a decree rendered in favor of the complainant.

The decision as rendered is one of the most far reaching that has been handed down to the metallurgical fraternity, and unless reversed or modified by a higher court will mean that a large percentage of the mills, both old and modern, which have been beneficiating ore since the date of the patent by means of cyanidation, will be directly obligated to the patentee for the process employed.

Balkan Mining

War has ever been a topic of large interest, but the changes which follow a war are usually of more real significance than the campaigns themselves. In 1898 the United States and Spain were drawn into what must in fairness be denominated a minor conflict, but the changes wrought by that war, especially in the United States, have been enormous, and the end is not yet. War stimulates powerful emotions. It stirs a people up as does nothing else, and it has often happened that this intellectual awakening brings more benefit to the vanquished than the nominal victory brings to the victor. Of more immediate interest, however, is the fact that war usually opens or closes great areas to development, and in this particular the Balkan war seems likely to be as potent as any.

In a brief but interesting paper read a few weeks since by Mr. Herbert K. Scott, before the Institution of Mining and Metallurgy, it was shown that Bulgaria includes considerable areas well situated for development and of large potential mineral wealth. The same statement regarding the other Balkan states could easily be supported, and yet the Balkan peninsula has for centuries yielded but insignificant amounts of mineral. At an earlier time, mining was extensive, but at present, aside from the Rumanian petroleum fields and the manganese mines along the Black Sea, little is heard of mining in the territory over which armies have been moving this past winter. It may be worth while to inquire to what extent the conditions that have retarded mining will be removed.

First and foremost must be placed the matter of government. It is notorious that poor government, almost no government, has obtained over much of the peninsula. There was not that security for life and property that is necessary before capital can be induced to enter a country. Furthermore, the Turks were not interested in mining. They knew little about it and cared less. They are a people

whose ideals lay in other directions, and to a large extent the same has been true of the other peoples of the Balkan states. The second great factor, therefore, was the fact that the thoughts and energies of the people were bent in another direction. This cuts deeper than appears at first glance. While in Bulgaria and Servia mining laws have been favorable enough, and deposits that in other countries would have been worked have been known, mining has not proved much more attractive to foreigners than to natives. Only those who tried to develop a new industry in an old country and have had to face the resultant labor problem, are prepared to appreciate fully why. The people of the Balkans have been devoted to agriculture and to war. The first was for the sake of making a living, and the second was for accomplishing the century-long purpose of expelling the Turk. The latter has been accomplished, and at the same instant, by a combination of circumstances, the country has filled with hundreds of experienced, hardy, and native miners.

Hard living conditions drove thousands of Greeks and Slavs to emigrate in the last quarter century. As is always true, the more enterprising were the ones to go, and, as is usually true with change of country, came change of occupation. The great bulk of these emigrants came to the United States, and, landing in big cities with few friends and little money, they in the main found places for themselves in the mines, mills, smelters, on construction gangs, and in various industries to which they had been strangers. How mightily they contributed to the rapid industrial progress of the United States is evidenced by the fact that 85 per cent of the meat packing, 80 per cent of the work on leather goods, 70 per cent of the mining of bituminous coal, 75 per cent of the iron and steel making, and similar percentages in other great industries, is conducted with foreign-born workmen. The average annual income of the immigrants in 1907 was approximately \$400. From time to time individuals, accumulating what was to them a competence, returned to their home country, freighted not only with money, but with new ideas, and they formed recruiting centres for further immigration. When the war came, whole regiments and shiploads of these peoples drew their pay and left to answer their countries' call. For a time production in the United States was crippled. In one district fourteen mines were closed for lack of labor.

From New Jersey to California, from Spokane to Bisbee, the drain was felt. These men are now in Thrace and on the Balkan peninsula. Whatever may be the outcome of the present fighting, when the armies are disbanded they must needs go to work, and since it is the nature of man to prefer his home country, it would be easy to man a number of mines and metallurgical works from foremen down with trained workers speaking or at least understanding English as well as their native tongue. This abundance of labor coupled with the desire for new things, and for industrial supremacy which may be expected to follow the successful completion of the war, removes the chief difficulties in the way of a highly successful and profitable mineral industry in the Balkans.

The Leaching of Copper Ores

By JOHN ROOKE-COWELL

The bodies of low-grade and, for the most part, oxidized copper ores which occur in the southwestern part of the United States, in Canada, Mexico, Central and South America, Australia, Africa, and in fact throughout the world, which, owing either to their inaccessibility, metallurgical condition, or their low copper content, cannot be profitably treated by smelting methods, and the huge accumulations of tailing from the great concentrating plants of the West, in which millions of pounds of copper is being lost every year, have turned the attention of metallurgists to the investigation of hydro-metallurgical or electro-chemical processes by which this copper may perhaps be profitably recovered at a small cost and added to the world's supply.

Leaching at Rio Tinto

At the mines at Rio Tinto the leaching of copper ores has for many years been successfully accomplished by a somewhat complicated and very lengthy process, by which the copper in the ore is converted into soluble copper sulphate by the natural oxidizing agencies of air and moisture and the copper precipitated from the solutions on iron. This process is too lengthy and entails the tying up of too much capital to find much favor under present commercial conditions. At Clifton, Arizona, the low-grade oxidized ores of copper have been for some years past leached with sulphuric acid manufactured on the ground at a small cost from a nearby deposit of pyrite, and the copper precipitated on scrap wrought iron and old tin cans.

Although the copper produced by this method is of inferior quality, this is the simplest and, where possible, the ideal method of leaching copper ores, but it is only applicable to oxidized ores and cannot be used to advantage in localities where sulphuric acid and iron are not obtainable at a moderate cost. The problem, therefore, which now confronts the investigator, and which during the past decade has given rise to half a hundred processes, most of which are now happily defunct, is to find a method suitable to both sulphide and oxidized ores of copper, by which the solvent may be regenerated at a small cost and the heavy expense of precipitation by means of iron eliminated.

Prospecting for Leases

With the thorough knowledge now possessed regarding the chemical reactions which occur among the compounds of copper, among themselves and also with relation to the known copper solvents and the associated minerals in the different ores, and the amount of accumulated data regarding the electro-deposition of copper from leaching solutions, and with the many improved mechanical devices at our disposal, the invention of such a process, with a fairly universal application, should not present any great difficulty. Yet the costly failures of many processes within the past few years have created a certain atmosphere of skepticism, and the

inventor of a new process is likely to be regarded in some quarters as a harmless crank, or as having sinister designs on the pocket of the investor.

Ammonia has been used as a solvent for certain oxidized copper ores, the copper being subsequently recovered as cupric oxide by simply heating the solution, but mechanical difficulties, the loss of ammonia during its operation, and the high cost of this solvent, have limited the usefulness of the process. Sulphurous acid, made by dissolving sulphur dioxide in water, has also been used as a solvent, the copper being recovered as cuprous oxide by heating the solution. In this, as in the ammonia process, the solvent is simultaneously regenerated with the precipitation of the copper. Sulphurous acid is an excellent solvent of copper ores, especially as it does not attack the other metals present with the same avidity as many other solvents. Only mechanical difficulties and the necessity for using extremely dilute solutions have prevented the successful application of the process. Sulphuric acid has been generally found to be the best and most convenient solvent for copper ores, while ferric sulphate and chloride, which have been found to readily attack certain chalcocite ores and act with less energy on chalcopyrite, have also been successfully used. In certain processes the copper in the ore is converted into a soluble sulphate by a careful roasting at a low temperature, and then leached with water; in others, a soluble chloride of copper is obtained by roasting the ore with common salt or passing free chlorine, obtained by the electrolysis of a solution of common salt, over the ore while it is being roasted. Sulphide ores for the most part require roasting before they can be successfully leached, but modern large-capacity mechanical roasting furnaces enable this to be accomplished at a low cost.

Solubility of Copper

There appears to be no great difficulty in dissolving the copper out of the ore, though cuprous oxide is soluble unless heat is applied, and chrysocolla (the silicate) is practically insoluble. The ore does not require a fine crushing, as is the case in the ores of gold and silver; about 10-mesh will generally be found sufficiently fine, while in some cases a reduction of the ore to pieces about one inch in size, and even larger, will be all that is necessary to obtain a good extraction of the copper. This naturally reduces the cost of crushing and does away with the difficulties of percolation encountered in other processes, as practically no slime is formed.

The action of the solvents on copper ores is increased by the application of heat to the ore charge, is extremely rapid, and the extraction of the copper from properly prepared copper ores is usually high. The numerous mechanical devices which are now available, such as stoneware and hard-rubber pumps for handling acid solutions, lead-lined pipes, and the several excellent non-corrosive compounds which

are now on the market for protecting the tanks and thus avoiding the necessity for using an expensive lead lining for the tanks, have done a great deal toward permitting the successful leaching of copper from its ores. In fact, it may be considered that most of the difficulties encountered in the actual leaching of copper ores have now been surmounted, and the others relegated to the precipitation of the copper from the solutions.

Practicable Methods

With the exception of the ammonia and sulphurous acid processes in which the copper is recovered as a high-grade oxide of copper, or those processes where the production of copper sulphate is the ultimate object, and neglecting the precipitation of copper by means of iron as generally too expensive, the only practicable methods in use for the recovery of the copper from its solutions are either chemically by the use of hydrogen sulphide, which is passed into the solution and precipitates the copper as copper sulphide, or electrolytically, by which the copper is obtained as cathodes of pure copper. In the former method the precipitation of the copper is rapid and complete, but at the same time the other metals of the acid group, such as arsenic, antimony, and bismuth, are precipitated with the copper, while other metals which are not precipitated in an acid solution, such as iron, continue to accumulate in the solution until it becomes so saturated and foul that it has to be thrown away and the whole of the contained acid lost. In any case, only the acid in combination with the precipitated metals will be regenerated, and so a constant addition of part of the acid at least will always be necessary. In some places the manufacture of hydrogen sulphide would be extremely costly.

Electro-Deposition of Copper

In the electro-deposition of copper from leaching solutions many difficulties have been encountered. They are partly due to the fouling of the electrolyte, owing to the accumulation of the sulphates of iron and other metals which make it necessary to periodically send some of the solution to waste, thereby causing a loss of all the acid; to the difficulty of finding a suitable anode for sulphate solutions other than lead, which is at present used but is rapidly oxidized; and to the reactions which occur among the foreign metals present in the electrolyte. Although a complete regeneration of all the acid is effected, and in fact when sulphur dioxide is injected into the electrolyte as a depolarizer, an excess of acid is obtained by its combination with the nascent oxygen liberated at the anode, so many reactions and counter-reactions occur among the foreign metals present in the electrolyte, and so much difficulty has been encountered in properly regulating the current density, that a great deal of electrical energy is wasted and the consumption of current is greatly in excess of that required for the actual electro-deposition of the copper. Theoretically, the electrical efficiency of the deposition of copper from sulphate solutions is 2.14 lb. per kilowatt-hour. In practice, from leaching solutions, only about one pound per kilowatt-hour, or about

50% of the theoretical efficiency, has hitherto been obtained. With a pure copper sulphate electrolyte, free from other metals, and the proper precautions taken to prevent the impoverishment of the copper ions around the cathode, there is no reason why at least 90% of the electrical efficiency, or about two pounds of copper per kilowatt-hour, should not be obtained. The difference between this and the theoretical is due to the resistance of the conductors. This would mean a reduction in the cost of the electrical installation and of the electro-deposition of the copper of about 50%, which would be of considerable importance in a large plant.

Advantage of Electrolytic Methods

Such a condition could be obtained if the electrolyte were freed from the presence of foreign and interfering metals, by chemical means, before being introduced into the electrolysis, instead, as is the practice at present, of precipitating the foreign metals when the electrolyte has become thoroughly saturated and foul and a great loss of electrical energy has already occurred. The great advantage of recovering the copper by electrolytic means is the complete regeneration of the solvent and the production of pure copper which can be readily marketed. The first cost of such an installation, especially if a high degree of electrical efficiency can be obtained, is not prohibitively high, as many people imagine, and the cost of precipitating the copper, especially where water-power is available, will in very few cases exceed one cent per pound. There seems every reason to believe that electrolysis will in time take the place of all other methods for the precipitation of copper from leaching solutions. Roasting, by rendering insoluble in acids many foreign substances which in the crude unroasted ore would be soluble, and by converting insoluble into soluble copper compounds, has been found beneficial before leaching. Yet in most cases where both the sulphides and oxides of copper occur in the same ore a preliminary concentration of the sulphides and the leaching of the oxidized tailing and roasted concentrate will prove most economical. Ferrie salts, which may be generated during the operation of the process, will dissolve part at least of the small amount of sulphides which escape concentration. Ores containing much lime are, for the most part, unsuitable for an acid-leaching process on account of the excessive consumption of the solvent, but in certain cases this has been overcome by roasting the ore at a low temperature and converting the lime into an insoluble sulphate.

Chemical Reactions

So thoroughly have the chemical reactions of the various copper compounds been investigated during the past few years that the process which will have the most general application in the treatment of low-grade copper ores is not likely to depend on the discovery of some new solvent or be a panacea for the treatment of all low-grade copper ores. It will comprise a simple, scientific, and economical arrangement of certain well known and thoroughly understood chemical and electrolytic reactions, and form a process capable of modification so as to meet

individual metallurgical and economical conditions. By taking advantage of modern labor-saving devices, and, so far as possible, eliminating the cost of chemicals, it will enable copper to be produced at a price which will prove profitable under almost all possible market conditions. Such a process would not only add considerably to the world's supply of copper by enabling the low-grade deposits and old tailing dumps to be profitably treated, but would prove a great boon to the small mine-owner, who is at present between the Scylla and Charybdis of courting almost certain disaster by erecting his own smelter, or of sacrificing a large part of his legitimate profits by selling his ore to customs smelters. There is no reason that such a process should not be used in the treatment of high-grade as well as low-grade copper ores, especially if freight rates to the smelter are high, and its introduction would lead to increased activity in all classes of copper-mining.

Concentration and Power for the Mt. Morgan Mine

Many changes in equipment at this great mine in Australia are under way, including the construction of a plant to deal with certain ores too highly silicious or too low in copper for profitable smelting, and the installation of a new power-plant. The following notes are from the annual report of B. Magnus, the general manager.

Concentrator

On the site of the old Mundie works, which have now been dismantled, the erection of a 500-ton per day concentrating plant is well under way. Although this plant is being erected for the treatment of this tonnage, the different units installed will be liberally designed, and it is expected that after working for some time, the capacity of this mill will at a small additional expenditure be increased to a much greater tonnage, probably 1000 tons per day. Before designing the plant, complete investigation was made of the best features in many of the large sized concentrating mills, so that they could be incorporated in the new plant. An experimental concentrating unit on a working scale has been running for some time, and results have been obtained which are better than those used when calculating the possible profit in the treatment of the low-grade unpublished ore reserves. This experimental plant will continue to operate for some months, so that when the new plant is started, investigations necessary to assure it being a success will have been made. Owing to the mineralization of the ore being so intimately disseminated throughout the silicious gangue, it is necessary to resort to exceptionally fine grinding before any concentration is attempted. This will, of course, add some expense to the cost of the treatment. Up to the present \$14,400 has been spent on the concentration experiment. Improvements now being made at some of the large American copper plants in the treatment of tailing will be investigated before any decision is arrived at as to what method will be suitable for the treatment of the tailing.

In the experimental plant some trial runs on

the tailing from the old Mundie and West works are being made. At the present time definite results cannot be given, but it is believed that these large tailing dumps will in the future become an asset to the Mt. Morgan company.

Power Plant

The erection of the boiler-house and engine-room is now well under way. The boiler-house will consist of large-sized units automatically fired with coal. Its arrangement is along the most up-to-date lines in modern power-plant construction. The engine-room will contain the following machines: two turbo-blowers, each one capable of delivering 40,000 cu. ft. of air per minute to the blast-furnaces at a pressure of 5 lb. per square inch. One mixed-pressure turbo-blower capable of delivering 10,000 cu. ft. of air per minute to the converters, at a pressure of 14 lb. per square inch. Three reciprocating air-compressors, delivering compressed air at 90 lb. pressure for the mine and general purposes. Three turbo-alternator rotary-converter sets of a combined capacity of 4000 kw. The existing blower-room will be used as a standby to take the place of the blast-furnace and converter blowers, in case of emergency. There will be sufficient power in the steam-driven units for all the requirements of the new plant, and will in addition have a 50% standby reserve in the electrically operated turbo-blowers. This portion of the new plant is expected to be ready early in the year unless some unforeseen delays arise in delivery of the machinery. The foundation for the three new blast-furnaces, each 28 ft. long, is now completed, and both the buildings and furnaces are under course of erection. It is anticipated that everything will be ready to blow in the new blast-furnaces in March next year. In the meantime the present plant will be kept going to its full capacity.

Gold production of Bendigo, Australia, for the first half of the current year was as follows:

	*Dividend-paying mines.	†Lansell group.	‡Non-dividend paying mines.
Ore treated, tons...	81,679	21,930	82,469
Gold yield, ounces			
(at \$18 per oz.)..	34,362	8,110	24,032
Dividends	\$283,000
Assessments	\$254,000

*13 mines. †5 mines. ‡65 mines. These include lessees.

Private mines and pyrite-treatment companies reported a yield of 10,996 oz. The most prominent producers were the Central Red, White and Blue, 13,065 tons yielding 6713 oz.; Golden Pyke, 7217 tons yielding 4516 oz.; Carlisle, 9825 tons yielding 3105 oz.; Virginia, 12,810 tons yielding 4064 oz.; North Bendigo, 4530 tons yielding 1921 oz.; South New Moon, 7591 tons yielding 1921 oz.; and Great Northern, 4181 tons yielding 1842 oz. Lessees' tonnages are not included. The total production of Bendigo to date is \$376,800,000.

Water used in April by 11 mining companies at Kalgoorlie amounted to 34,276,000 gal. in the mining and treatment of 146,247 tons of ore.

The proposed change of railway gages in Australia to the standard gage will cost \$177,600,000.

Leasing and Low-Grade Milling at Cripple Creek

By STEPHEN L. GOODALE

Two gentlemen, both of whom have been successful in the mining or allied businesses, have expressed to me in strikingly similar language an important point in their success. Several years ago a prominent mining engineer, a graduate of the Colorado School of Mines, said: "As I want to make money, I associate with people who have money." Only a few days ago a successful lessee at Cripple Creek said: "I want to make a success of leasing or mining, therefore I stay where the good mines are, and that is why I am at Cripple Creek, for Cripple Creek is where the live ones are." The mines of Cripple Creek are producing gold at the rate of about one and one-fifth million dollars a month, and

to assist in the examination, a man who is now leasing at Cripple Creek and has had long experience there, was well posted on this property before I visited it, his incentive being to know of any good opportunities for leasing. And this mine was practically without equipment and would need considerable expenditure for timbering and cleaning to get in working order.

Lease Contracts

Most of the leasing is on the basis of a flat rate royalty of about 25%; and in many cases whole properties are let on about this basis to one or more sets of lessees. Other mines lease on a sys-

GOLD DOLLAR SHAFT.

GOLD DOLLAR ORE-HOUSE.

still the people are complaining of things being quiet!

The present large production is due in great part to the development of the leasing system of operating the properties, and also in large part to the development of the means of treating low-grade ores. Both of these factors are being still further developed. A large number of miners are wandering about the properties where ground is offered for lease, poking into old workings in search for promising ground. Most of the men who are leasing are continually on the lookout for further lease opportunities.

Prospecting by Lessees

To illustrate this, I visited one old mine with two people who have a lease on it, to examine the property for a friend who was considering purchasing an interest in the lease. Two other miners were found in this mine, one of whom was prospecting an adjoining claim through this shaft; the other was simply poking about to see what he could find of interest with a view to a possible lease. I also found that a friend who accompanied him

tem of graded royalties, the royalties increasing with higher grade of ore, and some even increasing the rate if production exceeds a fixed sum per month. Lessees working on such a basis are not able to do any dead work, and can simply strip out what ore they can secure most easily without regard to developing more. This is said to be particularly true of the Stratton's Independence lease work.

In certain cases larger operators take a lease on the entire mine and sub-lease in blocks to smaller operators. In these cases it is usual to provide the sub-lessee with all equipment and supplies, such as tools, air-drills, compressed air, steel, powder, and the like, so that the sub-lessee risks only his time. The basis of settlement in such leases is first to take out of the returns from shipments the company royalty of 20 to 25%, then the original lessee and sub-lessee 'split the check'; that is, divide equally the remainder. This arrangement seems to work well. The miner can break so much ground and handle it with machine drills and good equipment that he can still make good wages in many places on this basis. Many prefer to do this rather

than pay a smaller royalty and work with hand steel.

Some of the larger companies have recently adopted this plan of 'staking the miner.' One company has opened to this scheme of leasing what is considered to be worked-out ground in its mine, and a number of sets of lessees are doing well for themselves. On these terms, which are more favorable than in the case of sub-leasing because the returns are not first diminished by deduction of any company royalty before the equal division between miner and company, the lessees have been able to do considerable prospecting and have opened some good shoots of ore. In most cases of leasing here the terms are not made sufficiently liberal to allow the ordinary lessee to undertake any considerable development work. So many miners are wanting to lease that the royalties are held high, and few, if any, concessions are offered to secure the per-

men can make wages if they get rock of \$7 grade to ship, and anything above that is 'velvet.' It can easily be understood that with so many miners on the ground hunting for leases, there are not many mines open for lease which are idle if there is ore in sight. It is often men who have worked in the mine for the company and who know of some promising stringer overlooked in company work or considered too small to follow who are most anxious to secure a lease.

Safety Measures

Before turning to the milling in the district, which is the other large factor, with leasing, in maintaining the great production, a few remarks may be made about some other points in mining. To a person used to seeing the many safeguards to men which have been adopted in many of the Eastern mines and industrial plants, it seems that

JO DANDY MILL, RAVEN HILL.

NICHOLS SHAFT OF EL PASO, BEACON HILL.

formance of development work on a large scale. On the other hand, leasing companies which are able to secure outside capital do not seem to be afraid to undertake more or less dead work in promising ground.

Economy of Lease System

There are so many ways in which lessees' expenses are lower than company costs in the same work that these men working on their own account can often make a place pay where it could not be made to pay for company work. Miners will often work harder for a lessee than for a company, and also will work with less equipment than would be demanded on company work. The companies are reimbursed for the large winnings of the fortunate lessee by the fact that other lessees may be making money for the company when they are not making any for themselves. Many of the companies are making money on the leasing basis which were losing money to work the mine on company account. Freight and treatment rates are now so much lower than formerly that lessees are able to ship ore of as low grade as \$10 per ton and realize a small profit, although, of course, this kind of material will not stand a heavy mining expense. This assists materially in prospecting, the rate on ore of up to \$10 value being \$4 for freight and treatment. When leasing on a dump, it is usually considered that

a 'Safety First' campaign would not be amiss in many of the mines and mills of Colorado. One of the striking things to a visitor at Cripple Creek is the number of maimed men to be seen there. The dangers in the gold mines and mills are in general different from those to be overcome in coal-mining and steel works, but they are, according to statistics, productive of a greater number of fatalities in proportion to the number of men employed. It would seem, therefore, that even more stringent safety measures should be adopted than in the case of coal-mining. Some improvements along this line have been accomplished, but much more remains to be done.

Many of the improvements along this line are incidental to changes designed to lessen costs, etc. For instance, many of the mines have changed from the use of cages for hoisting to the use of a moderate-sized skip. Of course, the skips are used primarily to reduce the cost of getting ore and waste handled, but the safety feature of the change would seem to be one of no little importance also. The miners riding in a skip with sides three or four feet high are protected to a considerable extent from accidents in the shaft. I know of at least several fatal accidents due to men falling when on a cage, or in some way moving enough to get caught in the shaft timbers, which accidents might have been prevented had a skip been in use in place of the

eage with a platform which is not protected.

There are minor points of interest in the equipment of most of the properties, large and small. There is a marked tendency toward the application of little devices to save labor and make work more efficient for an equal effort. A good many lessees are compelled to start their operations at least using the old Armstrong, back-breaking hoist. Almost every kind of hoisting rig can be seen at one mine or another from old to the most modern steam and electric hoists with steel head-frame as at a number of places, and occasionally with the hoist housed in a fine brick building as at the Gold Coin and the more recent Nichols shaft of the El Paso. On several of the smaller steam-hoists using buckets, a device is employed, or several devices, so that the engineer can close the door over the shaft, dump the bucket into the receiving bin or car, then release the bucket and let it down again without leaving his seat at the engine. At most places with bucket hoist this operation requires two trips from the engine to the shaft. This labor saving can be accomplished, as at one place, by ropes over pulleys to manipulate the door over the shaft, and by a steel 'V' frame hung from an outrigger which can be pulled by another rope under the bucket so that a chain and ball under the bucket will catch in the point of the 'V', and on releasing the hoisting cable the 'V' frame catches and overturns the bucket, drawing it away from the shaft and over the receiving car as it catches.

Surface Tramming

Motor cars have been adopted at many of the mines for surface hauling. Two views at the Gold Dollar mine are shown, where the equipment is good in certain respects. Surface tramming is done by electric cars using 3-phase, 550-volt motors. The three trolley wires are mounted in a channel built of boards which can be seen about two feet above the ground at the left of the track in the view. There is not much likelihood of anyone coming in contact with these wires accidentally, protected as they are in the deep channel by the overhanging boards. At the hoist is an electric annunciator with a number for each level, connected in the same way as the call-bells in a hotel, so that the engineer, instead of having to listen to a signal given by a number of rings of a bell, merely has to look at the annunciator to see what number has been called. This must leave his attention more free for other signals, such as those telling him what he has in the skip each trip, whether it is waste, or, if ore, to what bin in the ore-house to send it. This annunciator is also a safety measure, for the number is in sight until released by the engineer himself.

At many other mines, calls for the cage are given by flashing an electric light, this flashing showing in a light at the landing of each level so that the cage-tender knows of any call for the skip as well as the engineer; and the call has to be answered by a return flash from the engineer. This system has the advantage over the annunciator that the call may be known at any level, and the person giving the signal is answered by the engineer,

thus making it certain that his signal has been received.

In the view of the ore-house a bell can be seen above each sorting table. This is used to announce to the sorters into which bin ore is to be dumped at any time. Men working at other tables are in this way secured from interruption of their work by having to wait for the ore to be dumped after they hear the ore-car coming above. This view gives an idea of the interior of a modern Cripple Creek ore-house, with the men working at the sorting tables. Notice the excellent light obtained by windows in the roof as well as in the side walls,

DUMPING WASTE AT THE AJAX TO MAKE TAILING DAM.

and also the ample radiator provided for heating in winter. The heating is an important item, both that the ore shall not freeze in the bins, and that the men's hands shall not get too cold from handling it to do efficient work.

Types of Mills

A large number of mills are now working in the district, and several other large companies are experimenting on different treatments and considering the installation of mills. Metallurgically, the operating mills fall into two groups. The mills of one group practice coarse crushing only, have simple equipment and low initial expense; while those of the other group represent a heavy initial installation cost and grind at least a part of the ore very fine. Mills of the former type, such as the Wild Horse and Isabella (the Isabella not working just now) have been working for a long time in the district; while the latter type of treatment for the most part has been developed within the last three years.

The simpler type of mill is well represented by the Jo Dandy, of which a view is shown. This plant is treating a large mine-dump on Raven hill, and is right at its source of supply of ore. The ore is shoveled and trammed by hand from the dump to the mill, where it is dumped over a grizzly into a 10 by 20-in. Blake crusher set to break to about 1½ inches. Two stands of 16 by 36-in. rolls take the product of the crusher. The product of the rolls is elevated to a hexagonal trommel screen

8 ft. long and set with 1 ft. inclination in the 8 ft. This screen is 3-mesh No. 12 wire and runs at 15 r.p.m. Oversize from this screen returns to the rolls again; and the undersize is delivered to a belt-conveyor which transfers the material to the leaching vats. There are four of these leaching vats, 5 ft. deep and 30 ft. in diameter, and of about 125-ton capacity, in use. In charging the material into the vats, considerable care must be exercised to avoid channeling later on account of the large range in size of the material treated. Solution is first applied from below for the same reason. But one strength of solution is used, from $1\frac{1}{2}$ to 2 lb. per ton. The first solution stands on the ore for 12 hours and is then withdrawn and the ore allowed to drain for aeration. The cyanide leaching treatment is continued for about three days, the vats being allowed to drain well between applications of solution to promote oxidation as thoroughly as time permits, the complete cycle for one charge being about seven days. Just enough water wash is used at the last to keep up the solution in the mill; and then the exhausted ore is shoveled out of the vat by contract and trammed in hand-pushed cars to the dump. This would seem to be one of few mills in the district not troubled by a lack of convenient dumping room.

The pregnant solutions are precipitated by zinc shavings in the usual 6-compartment boxes, the barren solution going to the storage vats. The cyanide solutions are made up to strength by adding the salt at the head of the zinc-boxes to keep the precipitation good.

Thomas Kavanaugh, who is operating both this and the Homestake plants, says the rock is a sylvanite ore containing considerable arsenic and manganese and is extremely refractory, with not over 10% of free gold. He says he is securing about an 85% extraction and that the ore runs about \$2 grade, which is an extremely good result on such coarse refractory material. Mr. Kavanaugh has but recently started up the Homestake plant. This and the Wild Horse and Dante mills are following nearly the same practice; but they are working on oxidized material, whereas the Jo Dandy dump ore is said to be refractory.

Position of Gold Minerals

The explanation of the development of this simple inexpensive treatment lies in the position of gold minerals on the seams in the rock, along which seams the rock almost invariably breaks in crushing. If it were not for this distribution of the gold, fine grinding of the material would be required, for the rock itself is usually extremely dense. It may even be said that if it were not for this fact of the seams containing metal and being extractable largely on crushing, it is probable that no such development as the present could ever have occurred at Cripple Creek. The ore content, considering the ore-shoots as a whole, are usually too low to be commercially valuable without screening and sorting and saving for the most part the fine only, and discarding the coarse material. Of material which is hoisted from the ore-shoots themselves, not much more than 20 to 40% on the average is

saved as ore. As the waste from this is in addition to the large amount of waste raised from ordinary development work, the size of the Cripple Creek waste dumps is enormous. But it is far cheaper to dispose of this large mass of low-grade coarse rock by leaving it on the surface at the mine than to handle it further as would be necessary if the mineral content were uniformly distributed throughout the rock, and all the rock had to be crushed and milled.

Modern Mills

The later more elaborate mills can be considered to be a development of the simpler practice above outlined. Without going into the detail of any one mill, a few general points of the treatment may be mentioned. The practice has been adopted at two places of breaking the rock to walnut size, then screening through a finer screen of from 4 to 8 mesh, and saving only the fine material for further treatment. When the coarse material is muddy, it is washed to recover the fine material. This practice saves perhaps 20 to 30% of the fine material out of ore which may assay perhaps \$3 before breaking, the portion saved being of some \$8 or \$10 value. The erection of a crushing and screening unit to apply this treatment preliminary to shipment is being considered by other mine managers, and careful experiments are being made to determine just what screen and crushing sizes are best and how much washing should be applied.

The treatment at one plant includes grinding of the above material in cyanide solution in roller mills, then concentrating on Wilfley tables. The tailing from these tables after dewatering is discarded, as it is of such low grade as to make the leaching cost about as much as it would return. The concentrate, after being cleaned on a second set of tables, is shipped to the smelter; and the middling from this set of tables is reground in a tube-mill and cyanided as slime. The slime overflow from the sand tailing is also treated by agitation. Gold-bearing solution is precipitated with zinc dust. The details at the large new mills vary greatly; but the above may be considered to be an outline of the treatment adopted.

Most of the mills are facing difficulties in disposing of their tailing. The finely ground material discharged while wet tends to spread over the ground and not to stack well. One of the mills at present is storing the tailing in a deep gulch behind a dam of waste rock from the mine. The dam is being built by means of an aerial tramway dropping rock where needed for the purpose.

From the present situation in the district, it seems probable that both leasing and the milling of low-grade ores in mills situated near the mines are to be greatly extended in the next few years.

The Cobar copper and gold field, New South Wales, to the end of March 1913 has produced approximately 103,000 tons copper, 500,000 oz. gold, and 1,250,000 oz. silver, valued at \$38,500,000.

Iron-ore shipments on the Lakes in July totaled 8,204,416 tons, against 7,600,233 tons in that month of 1912.

Under-Estimating the Cost of Milling Plants—IV

By A. SYDNEY ADDITON

Building construction includes many sources of excess cost. Most common of these are the failure to provide detailed working drawings. When such drawings are furnished, the failure to stick to them and the taking off of the bill of material from sketches instead of from detail drawings. The usual estimate comprises the cost of main buildings, housing specified equipment, and the omissions in the equipment estimate indirectly affect this item. In addition, upon making an installation it is found that, besides the buildings estimated, it is necessary to provide some or all of the following; storehouses, machine shop, hoist-house for incline tram, transformer house, enlarged assay office for laboratory, temporary or permanent office, enlarged or new bunk-houses, special bunk-houses, individual dwellings or cabins, enlarged or new dining and cook-houses, stables, and cement houses. Such estimates usually fail to sufficiently cover the details of buildings, such as floor systems, stairways, gangways, platforms, temporary and permanent braces and staging, motor rooms, foreman's office, or report and testing rooms, windows and doors in sufficient number, material for appliances for use in constructions, such as gin poles, trucks, dollies, falls, and bars. Estimates of buildings are sometimes made by allowing a certain amount per square foot of ground covered, according to style of building, but there can be no adequate basis for such figures. Aside from these general points, the usual excess cost of material for buildings can best be discussed under the headings of lumber, iron and hardware, and structural steel.

Bill of Lumber

The first error usually arises at the start in taking off the bill of lumber from the plans. This is done from insufficiently detailed drawings, too much being held up in the mind of the estimator, while his pencil records the items. Too little attention is paid to lengths, and after the bill has been taken off it is customary to add a certain amount of lumber to cover errors and possible omissions and to "make sure of the amount needed." Here large errors are made, not always in the amounts, but in the specification of sizes and lengths. This results in two or three subsequent orders being necessary in order to complete the buildings while a large amount of lumber remains unused in the yard. It is necessary to make additional allowance in a most carefully computed bill, as it is impossible to foresee the exact amount of waste, bad lumber, minor alterations, and additions. But in making this allowance great judgment must be used. An experienced engineer knows that there is an allowance factor for every size and length of lumber in the bill, and by using such factor but little error is possible if the bill has been carefully taken off. In placing orders for lumber, one of the specifications should be the weight per square foot. There is a big difference in first cost as well as in erection charges, between

lumber weighing 8 lb. per foot and that weighing 2½ lb. per foot. Delivery should be timed to suit the readiness of the plant to receive, otherwise large sums can be easily added to cost. Perhaps the greatest amount of added cost in this lumber item occurs on account of improper delivery and improper caring for the lumber at the site. In order to save this the estimate should include the cost of the proper yarding of the lumber. This is itself an added cost in most estimates, but it is insignificant when compared with the cost of failure to provide for it. When lumber is delivered at the site, suitable and roomy yards should be ready, and as the lumber is unloaded every stick sorted out and piled with reference to the size and length, checked off, and reported to office daily. When it is possible to prepare a suitable yard at each grade level, the lumber for use at this grade (or the next grade below) should be yarded there, as far as possible, all other lumber going to general yard. The reasons for this are important ones. (a) The time spent in hunting for lumber when wanted, handling over piles and piles to get what is being looked for, is in many cases, greater than the time required to frame the piece and erect it. Besides this, the hunting is usually done by a high-priced carpenter who should be at work with his tools.

Time Losses

It is not unusual for a \$6 per day man to spend 15 minutes getting a piece of 2 by 6 in. by 20 ft. long, thus adding 1c. per foot or \$10 per thousand, to the cost of erection, instead of a \$2.50 laborer getting the piece from its correctly placed pile in 2 minutes, costing but 1/20c. per foot or 50c. per thousand. (b) Lumber used for parts of construction for which it was not ordered or allowed is another reason. Carpenters or their helpers go to mixed piles for certain lengths of lumber and, finding that they cannot be conveniently reached, take a longer piece that will cut to the length wanted, but wasting the cut-off and leaving it in the yard, a piece of lumber that will not be of any use later on in that part of the building where the long lengths are cut up. This results in additional 'rush' lumber orders nearly every day toward the close of the building operations, often having to be shipped in less than carload lots and causing expensive delay. I might add that this sometimes happens even when the lumber is sorted and piled properly, but can be easily avoided by providing the chief carpenter or the framers with a list of the sizes and lengths to be used in the job in hand. This is easy and it costs nothing at the time when the bill is taken from the drawings.

The estimating of the amount of corrugated iron needed by computing the number of squares to be covered is the usual method, but this will not suffice and insures an added cost. The bill for this material must be taken off even more carefully than the lumber bill, by following the details of the construction of the frame, and specifying the lengths neces-

sary to cover each wall and roof with the least amount of waste. This can easily be done and in designing the frame for a corrugated iron building, standard lengths of iron must be considered in spacing the purlins, girts, and openings. After the bill is properly taken off, the next point to watch is that proper delivery is made to the site, as added costs can be incurred in the same way as in the case of improperly delivered and improperly cared for lumber. Lengths should be piled together at the grades most convenient for use for that portion of building for which they were ordered. Another small item which is almost inevitably forgotten until wanted, is the proper barbed nails and lead washers for putting on the corrugated iron. Bar iron: the usual estimate lumps this item at so many bars of various sizes, "in order to have an assortment in case it should be needed." The tonnage ordered is often excessive while the sizes wanted are short and have to be rush-ordered. It takes but a few minutes to run through the working drawings and take off a true list of the bar iron required; by adding a certain allowance, using the proper factors for each size, the added cost will be avoided.

Quantity of Nails Required

The quantity of nails is usually guessed at, with the result that if sufficient weight is estimated, the sizes wanted are incorrect and more of certain sizes must be sent for, while a quantity of other sizes remains in the storehouse. There is an accurate set of factors for nails, based upon the amount and sizes of lumber to be erected available. This was compiled and published by Charles T. Hutchinson in the *Mining and Scientific Press* of October 28, 1911.

Builders' and miscellaneous hardware is but a small item but is usually entirely overlooked in an estimate, especially the hardware necessary for the houses and cabins supplementing the main buildings. In the case of a steel-frame building, the estimate for the actual material cannot be far wrong, as it is necessary to prepare detailed plans, all parts being framed and marked before shipment to the site, and their cost is known at the time estimate is made. There should, therefore, be no added cost for material used in the wrong place but the delivery is as important, or more so, as in the case of lumber. It is expensive to find that a heavy member needed at the top of the plant has been delivered at the lowest level, but it is not unusual. Great care employed in checking parts as delivered and placing them on the grade needed, or next grade above, will save a heavy excess labor cost. It can readily be seen how much excess cost may be incurred in the single item of building material.

Permanent Utilities

The excess cost of utilities about a plant is necessarily controlled by its size, the distance from the mine, and the adequacy of the utilities already available. Estimates of plant usually fail to cover this item, so that whatever is installed of this kind is an added expense. The principal items have been covered in a general way above under 'Utilities During Construction,' and are discussed in more detail later.

The pipe and fittings for a water system, as speci-

fied in the usual estimate, include a main line from the source of supply through the plant, but the distribution of the water to the many places where it is needed is usually omitted, mainly because the actual position of the taps is not shown on the drawings. An estimate of the cost of a lot of pipe and fittings has to suffice. As necessity arises, the distribution system is extended, much to the embarrassment of the one responsible for the supply of material provided. It is found that water is required not only in the plant, but in other buildings such as the laboratory, stables, houses, cabins, and bunk-houses, and is usually provided, but the expense becomes another item of excess cost.

Fire System

Fire system, which is an important item, is nearly always left out and is later installed at an added cost. In some instances it is thought to cover this item by simply placing a few extra plugs for hose at points in the building on the main water line, but this is always found inadequate, especially after there has been a fire scare, or after an insurance inspector has visited the plant. The result is that an adequate system is installed, with main lines and laterals, and with plugs for hose placed outside of buildings, to covering protection to other than main plant. Hand grenades and buckets are usually placed inside of the plant and other buildings. All of this should have been included in the original estimate, thus avoiding this additional cost.

When the laboratory and assay plant is being built at or near the mine, this cost item is usually omitted from the estimate, as "the mine assay office will be used." It is very seldom that an assay office that has been laid out for the work of the mine is at all adequate for the work of a milling plant. Besides the greatly increased number of daily assays required there is a large amount of laboratory work to be done, for which the mine assay office is not equipped. There results the necessity of building a new assay office for the mill, or enlarging the old one, either alternative constituting another excess cost.

The same remarks can be applied to the office building as to the laboratory. Additional building, either as additions or separate constructions are found necessary, as well as additional equipment. Especially is this true for accommodation during construction work and the estimate that has not provided for this will have to bear an additional excess cost.

Superintendence

This refers to superintendence during construction and covers the salary of the constructing engineer, and the cost of his assistance on the building work and in the office. By referring to 'Organization' it will be seen that this is not a small item. It is usually covered in an estimate by combining the salary of the engineer with a certain allowance for the maintenance of the office. This amount is seldom sufficient to cover the cost of the necessary traveling expenses, to say nothing of other office expenses and incidentals. The cost of superintendence is much greater during construction work than

during operation, and nearly the whole amount can usually be put down as an excess cost.

The cost of supplies during construction work aggregates quite an amount, and is usually left out of the estimate entirely. Such items as coal for blacksmith, oil and waste for machinists, special tools for mechanics, carpenters, and pipe fitters, feed for teams and other horses, gasoline and repairs for automobiles, paint, putty, oakum, white lead, brushes, grease, tar, pitch, rope, chain, babbitt, solder, kerosene, packing and gasket rubber, lanterns, torches, extra fittings, fuel for office and bunk-house, steel for picks, and office supplies total up to a large sum.

Labor

The exact amount of skilled and unskilled labor necessary for installing equipment is somewhat difficult to estimate. It differs from estimating material, owing to the consideration necessary to be given to the 'human factor.' However, an estimate can be made that will work out to within one or two per cent of the actual cost, if sufficient thought is given to the details of labor necessary, when preparing the figures. It is customary to arrive at the estimate of labor either from the advice of machinery dealers, or from the past experience of estimator. Both are generally at fault; the first through the lack of experience in the field on actual construction, or from off-hand guessing, the second through failure to correct his figures to suit the conditions governing the case in hand. Both systems lead to excess cost. In addition to these two causes some other important reasons for excess cost of labor are: (1) error in the selection of a foreman, and failure to recognize his importance and responsibility; (2) lack of perfect organization; (3) failure to recognize the importance of many of the factors discussed above in leading to excess cost, and to make proper allowance for the same; (4) failure to provide a proper number of unskilled laborers to assist the skilled laborer; (5) the employment of a foreman or laborers for any other reason than because of their efficiency; (6) failure to make men contented.

Importance of the Foreman

The selection of a foreman is of the greatest importance. The cost of a piece of work can easily be doubled by the wrong man, or the right man wrongly handled. Surprising as it may seem, the correct time to select the foreman, in order to insure efficient labor results, is at the time the estimate is being prepared. Certain qualifications in a foreman are highly important. He must be able to do and to have done any portion of the work he is called upon to superintend, for only in that case can he intelligently direct, or know what constitutes a day's work. This is not a position for young college graduates, regardless of how valuable his services may be at some other work. He must understand men, and how to handle them. All men cannot be handled alike. To get greatest service from some they must be 'jollied' or praised, other must be 'cussed,' others must be left alone, and the man who cannot quickly distinguish these traits in his

men is an expensive foreman. He must be a man in whom utmost confidence can be placed. He must be loyal to the engineer in charge. The importance of selecting such a man at the time of making the estimate is this: His knowledge of the work may be no greater than that of the engineer making the estimate, but in calling him to assist in making the estimate of labor, confidence in him is displayed, and if he says that certain work can be done for a certain amount, he will see to it that, when the work is done, it does not cost more. He must be given an absolutely free hand in employing and discharging his men. It is often not convenient for him to hunt for men, and this may be done for him, but no one must dispute his authority in discharging. Take quick action when he asks for more men, and leave it to him to reduce the crew at earliest possible moment.

Organization of the Working Force

The failure to perfect the organization of the working force insures an added cost in the same way as does the failure to properly yard and care for equipment and supplies. Every man must have certain work for which he is responsible, and there must be no question of authority in any department. Excuses must be entirely eliminated. When excuses get on the payroll excess cost piles up very fast. The failure to properly proportion a crew with skilled and unskilled labor is a most common source of excess cost. It is quite usual to see a high-priced mechanic hunting for a tool, a part, cleaning rubbish from about his work, uncrating a piece of machinery, or tugging on a chain-block or truck, while the work of preparing the foundations and getting everything ready to quickly put the pieces in place, is waiting. A tank-builder will often be found uncrating or uncrating tank material, instead of putting it together. High-priced carpenters are often found nailing on siding or laying rough floor. There is a certain amount of work about every construction that can be done best, and another part that can be done as well, by common labor. Every stroke of work that is done by skilled labor is adding unnecessary cost. On the other hand, there is comparatively little construction work requiring skilled labor that can be done by common labor, and every attempt to so use the common labor will also insure added cost. Too often the efficiency of the laborer is not the only reason for his employment on the work. Friends of officers or employees, friends of friends, or men put on construction because they are wanted later in operating the plant, all find employment on work for which they are not qualified, and thus the added cost is swelled. No man will give a fair day's service who is not properly taken care of and treated like a man. He must be well fed and housed. His reasonable personal wants must be attended to. Much excess cost is caused by poor bread on the boarding-house table or too hot or too cold a place in which to sleep.

Another point in connection with labor in general is worth mentioning. In making calculations for the service of a pump, a compressor, or other piece of machinery, the efficiency of that machine is taken into account. But in calculations for men to do

work, they are accepted at rated capacity. When 100 men are hired at \$2.50 per day, it is evident that not all of these men do the same amount of work. They do work just as the machine does, according to their design or make, all having their individual factor of efficiency. This ranges from, say 30% (few fall below this) up to 100%, perhaps averaging 70%. This average of 70% is satisfactory, but when the number of men on the payroll whose efficiency is below 70% gets to be greater than the number whose efficiency is above, excess cost is being incurred. The regulation of this balance is in the hands of the foreman.

So much for the reasons for excess cost due to labor in general. To this may be added a long list of items of work to be done during construction, which are not included in the usual estimate, in addition to what has been mentioned above. Some of these are: assistance to be given teamsters in unloading; handling of equipment and material to yards or storehouses; handling of equipment and material from yards and storehouses to points of use; unboxing and uncrating equipment and supplies and removing rubbish; checking and marking; cleaning of parts and preparing them for assembly; chipping, drilling, and cutting; rectifying errors of manufacturers; shop-work, making of rods and bolts; carrying to and from shop; labor for erection or use of material not included in estimate, as above; labor for erecting or using material not included in estimate; care of office and other quarters; care of horses (other than regular freight teams); messengers; and others according to circumstances. Taken altogether then, it will be found that probably the greatest amount of excess cost can be attributed to labor alone.

Miscellaneous

Under this there comes a long list of all sorts of items, more or less expensive according to the conditions existing and how thoroughly the estimate has been detailed. A piece of road to be built here or there; a ditch to be built, a bank to be raised, a dry wall to be made, furnishings for houses and cabins, equipment for the boarding-house, teams and wagons, and many other items are sometimes claimed to be 'unforeseen necessities' but they all increase the excess cost.

Freight on the material and equipment specified in the estimate, is an item that should give rise to very little added cost, but it often does, in the following ways: failure to secure f.o.b. prices on small items of material, thus allowing the dealers to add hauling charges at point of shipment; failure to arrange for shipment in manner to avoid less than earload rates on some of the equipment and material; failure to allow for switching charges at the railroad point; demurrage; lumber freight estimated on basis of lumber weighing $2\frac{1}{2}$ lb. per foot, when lumber delivered weighs 6 lb. per foot; less than earload freight rates on equipment and material not included in the estimate. Estimate of the hauling cost if done by company teams, usually fails to cover wear and tear and repair of wagons, repair and wear and tear of harness and other equipment, horse-shoeing, roadwork, forwarding at railroad, and

accommodations for horses. If hauling is contracted for much the same added cost may occur as in the case of freight. In addition to these must be added the cost caused by continual concessions granted to teamsters and delay of work owing to failure to get teamsters to bring from the railroad material most needed at time wanted. Hauling from the railroad, if at any distance, is really one of the most annoying parts of the constructive work and is extremely difficult to estimate correctly. Liberal allowances must be made. Because a freighter agrees to deliver equipment and material from the railroad at so much per ton is no reason for believing that this is what it is actually going to cost. Inability to secure teams, having teams quit hauling at critical points in the construction work, and losses due to damaged material owing to improper loading or hauling, are all additional items of cost. The added cost directly due to these items is often but a small part of the real excess cost they cause as they effect to a greater or less extent all parts of the construction. I have gone into the factors which unite to produce a total cost of construction work that is in excess of the estimated cost in detail in order to indicate how easily many of them may be overlooked and yet how important they may be in swelling the final cost. If my discussion proves of service in aiding other engineers in avoiding the under-estimation of the cost of construction work which may be under their charge, and in dissuading owners from adopting plans which appear economical but are in reality unduly expensive, I shall feel amply repaid.

Mineral Production of the Philippines

The following figures for 1912 were compiled by the Bureau of Science at Manila:

Products.	Quantity.	Value.
Metallic:		
Iron, metric tons.....	141	\$24,636
Silver, fine ounces	7,121	4,332
Gold, fine ounces	27,582	570,212
Non-metallic:		
Coal, metric tons	2,720	10,100
Clay products	226,500
Lime	46,013
Sand and gravel	234,375
Stone	325,524
Salt, metric tons	19,147	287,255
Mineral water, gallons	27,925
Total	\$1,756,872

The total value in 1911 was \$1,413,205, the main increase being in gold output.

During May the railways of the United States received for their services to the public an average of \$8,230,000 per day; it cost to run their trains and for other expenses of operation \$5,920,000 per day; their taxes were \$341,500 per day; their operating income was \$1,972,322 per day for the 220,897 miles of line reporting, or at the rate of \$8.93 for each mile of line for each day. Thus for every six dollars of their earnings which remained available for rentals, interest on bonds, appropriations for betterments, improvements and new construction, and for dividends, the railways had to pay more than one dollar in taxes.—*Bureau of Railway Economics.*

Pumping at the Comstock

By A. M. WALSH

The water question has always been a serious one at the Comstock mines, where the mine water has a temperature ranging from 130 to 155°F., and is contaminated with alum and acid. The temperature of the air on the pump station varies from 105 to 125°F., and it can be readily seen that ventilation is just as important as pumping.

By arrangement with the mining companies, the United Comstock Pumping Association is doing its

The installation at this station consists of three horizontal turbine pumps. These pumps were manufactured by the Byron Jackson Co. and are driven by three General Electric 200-hp. 440-volt motors. Each unit has a capacity of 1500 gal. per minute. Two units are in constant operation and the third unit is an auxiliary to be used in case of accident to either of the other units. This station is pumping approximately 2100 gal. of water per minute to the

Riedler station. Lubricating oil in motor and pump bearings varies from 150 to 160° Fahrenheit.

The installation on the Riedler station, 2000-ft. level, consists of three 6¹¹/₁₆ by 24-in. Riedler pumps. They are the horizontal duplex double-acting plunger type and are driven by three Westinghouse 200-hp. 2200-volt motors. Each unit has a capacity of 1500 gal. per minute. These pumps were designed by Riedler and manufactured by the Allis-Chalmers company. Two units are in constant operation and the third unit is an auxiliary to be used in case of accident to the other units. This station is pumping approximately 2100 gal. per minute into the Sutro tunnel which connects with the C & C shaft at its 1600-ft. level. The main part of this drainage tunnel is 20,489 ft. long and cost \$2,100,000, it being finished during 1879.

The diagram shows two 16-in. air-lifts immediately below the Riedler station. Under the former management the turbines at the 2310-ft. station pumped the water to the lower Riedler tank. The water was then pumped an additional 10 ft. to the upper Riedler tank with two 16-in. air-lifts. This has been rearranged so that the turbines at the 2310-ft.

best to handle the water, and the following notes and illustrations should give an idea of the work done.

Electric Turbine Pumps
